

Advanced Bash-Scripting Guide

Advanced Bash-Scripting Guide	1
An in-depth exploration of the art of shell scripting	1
Mendel Cooper.	
•	
<u>Dedication</u>	3
Part 1. Introduction	13
Chapter 1. Why Shell Programming?	15
Notes.	
Chapter 2. Starting Off With a Sha-Bang	17
2.1. Invoking the script	21
Notes.	21
2.2. Preliminary Exercises	23
Part 2. Basics.	25
Chapter 3. Special Characters	
Notes.	44
	4-
Chapter 4. Introduction to Variables and Parameters	45
4.1 West-11- Cal-44-45	45
4.1. Variable Substitution	
Notes	49
4.2. Variable Assignment	51
4.2. Valiable Assignment	31
4.3. Bash Variables Are Untyped	53
10. Dusii variables ilie Ontypea	
4.4. Special Variable Types	55
Notes.	
	-
Chapter 5. Quoting	61
5.1. Quoting Variables	63
Notes	
_	
5.2. Escaping	65
Chapter 6. Exit and Exit Status	71
Chapter 7. Tests	73

7.1. Test Constructs	75
7.2. File test operators.	83
Notes	
7.3. Other Comparison Operators	
Notes	92
7.4. Nested if/then Condition Tests	93
7.5. Testing Your Knowledge of Tests	95
Chapter 8. Operations and Related Topics	97
8.1. Operators	99
Notes.	
8.2. Numerical Constants	107
Part 3. Beyond the Basics	109
Chapter 9. Variables Revisited	111
9.1. Internal Variables	113
Notes	
9.2. Manipulating Strings	131
9.2.1. Manipulating strings using awk.	
9.2.2. Further Discussion.	
Notes.	
	100
9.3. Parameter Substitution	
Notes	14/
9.4. Typing variables: declare or typeset	149
9.5. Indirect References.	153
9.6. \$RANDOM: generate random integer	157
Notes.	
9.7. The Double Parentheses Construct	169
Chapter 10. Loops and Branches	171
10.1 Loops	187
Notes.	
<u>110100</u>	103

10.2. Nested Loops	187
10.3. Loop Control	189
Notes.	
10.4. Testing and Branching	193
Chapter 11. Command Substitution	201
Notes.	206
Chapter 12. Arithmetic Expansion	207
Chapter 13. Recess Time.	209
Part 4. Commands	211
Chapter 14. Internal Commands and Builtins	219
14.1. Job Control Commands	247
Notes.	250
Chapter 15. External Filters, Programs and Commands	253
15.1. Basic Commands	255
Notes.	260
15.2. Complex Commands	261
Notes.	270
15.3. Time / Date Commands	271
15.4. Text Processing Commands	275
Notes.	294
15.5. File and Archiving Commands	295
Notes.	311
15.6. Communications Commands	
Notes.	326
15.7. Terminal Control Commands	327
15.8. Math Commands	329
15.9. Miscellaneous Commands	339
Notes.	351

Chapter 16. System and Administrative Commands	353
16.1. Analyzing a System Script	381
Notes.	
Part 5. Advanced Topics	383
Chapter 17. Regular Expressions.	385
17.1. A Brief Introduction to Regular Expressions	387
Notes.	390
17.2. Globbing Notes	
Chapter 18. Here Documents.	
Chapter 16. Here Documents	
18.1. Here Strings.	403
Chapter 19. I/O Redirection.	407
19.1. Using exec	411
Notes.	414
19.2. Redirecting Code Blocks	415
19.3, Applications	421
Chapter 20. Subshells	423
Notes.	427
Chapter 21. Restricted Shells.	429
Chapter 22. Process Substitution	431
Notes.	433
Chapter 23. Functions.	435
23.1. Complex Functions and Function Complexities	439
Notes.	
23.2. Local Variables	449
23.2.1. Local variables help make recursion possible.	450
Notes	451
23.3. Recursion Without Local Variables	453

Chapter 24. Aliases	457
Notes.	459
Chapter 25. List Constructs	461
Chapter 26. Arrays	465
Chapter 27. /dev and /proc	491
<u>27.1. /dev</u>	493
Notes.	
<u>27.2./proc</u>	
Notes.	502
Chapter 28. Of Zeros and Nulls	503
Chapter 29. Debugging	507
Notes.	
Chapter 30. Options	517
Chapter 31. Gotchas	519
Notes.	526
Chapter 32. Scripting With Style	527
32.1. Unofficial Shell Scripting Stylesheet	529
Notes.	531
Chapter 33. Miscellany	533
33.1. Interactive and non-interactive shells and scripts	535
33.2. Operator Precedence	537
Notes.	539
33.3. Shell Wrappers	
Notes.	545
33.4. Tests and Comparisons: Alternatives	547
33.5. Recursion	549
33.6. "Colorizing" Scripts	553
Notes.	

33.7. Optimizations	567
33.8. Assorted Tips	569
33.8.1. Ideas for more powerful scripts	
33.8.2. Widgets.	
33.9. Security Issues	581
33.9.1. Infected Shell Scripts.	581
33.9.2. Hiding Shell Script Source.	581
33.9.3. Writing Secure Shell Scripts	581
Notes	581
33.10. Portability Issues	583
33.11. Shell Scripting Under Windows	585
Chapter 34. Bash, versions 2 and 3	587
34.1. Bash, version 2	589
Notes.	593
34.2. Bash, version 3	595
34.2.1. Bash, version 3.1.	596
34.2.2. Bash, version 3.2	597
Chapter 35. Endnotes	599
35.1. Author's Note	601
Notes.	601
35.2. About the Author.	
Notes.	603
35.3. Where to Go For Help	
Notes.	605
35.4. Tools Used to Produce This Book.	
<u>35.4.1. Hardware</u>	
35.4.2. Software and Printware	607
35.5. Credits	609
35.6. Disclaimer	611

Advanced Bash-Scripting Guide An in-depth exploration of the art of shell scripting

Version 5.1.06

18 January 2008

Mendel Cooper

thegrendel@theriver.com

This tutorial assumes no previous knowledge of scripting or programming, but progresses rapidly toward an intermediate/advanced level of instruction . . . all the while sneaking in little snippets of UNIX® wisdom and lore. It serves as a textbook, a manual for self-study, and a reference and source of knowledge on shell scripting techniques. The exercises and heavily-commented examples invite active reader participation, under the premise that the only way to really learn scripting is to write scripts.

This book is suitable for classroom use as a general introduction to programming concepts.

<u>The latest update of this document</u>, as an archived, <u>bzip2-ed</u> "tarball" including both the SGML source and rendered HTML, may be downloaded from the author's home site. A <u>pdf version</u> is also available (<u>pdf mirror site</u>). See the <u>change log</u> for a revision history.

For Anita, the source of all the magic

Table of Contents

Part 1. Introduction

- 1. Why Shell Programming?
- 2. Starting Off With a Sha-Bang
 - 2.1. Invoking the script
 - 2.2. Preliminary Exercises

Part 2. Basics

- 3. Special Characters
- 4. Introduction to Variables and Parameters
 - 4.1. Variable Substitution
 - 4.2. Variable Assignment
 - 4.3. <u>Bash Variables Are Untyped</u>
 - 4.4. Special Variable Types
- 5. **Quoting**
 - 5.1. Quoting Variables
 - 5.2. Escaping
- 6. Exit and Exit Status
- 7. Tests
 - 7.1. Test Constructs
 - 7.2. File test operators
 - 7.3. Other Comparison Operators
 - 7.4. Nested if/then Condition Tests
 - 7.5. Testing Your Knowledge of Tests
- 8. Operations and Related Topics
 - 8.1. Operators
 - 8.2. Numerical Constants

Part 3. Beyond the Basics

- 9. Variables Revisited
 - 9.1. Internal Variables
 - 9.2. Manipulating Strings
 - 9.3. Parameter Substitution
 - 9.4. Typing variables: declare or typeset
 - 9.5. <u>Indirect References</u>
 - 9.6. <u>\$RANDOM</u>: generate random integer
 - 9.7. The Double Parentheses Construct
- 10. Loops and Branches
 - 10.1. <u>Loops</u>
 - 10.2. Nested Loops
 - 10.3. Loop Control
 - 10.4. Testing and Branching
- 11. Command Substitution
- 12. Arithmetic Expansion
- 13. Recess Time

Part 4. Commands

- 14. Internal Commands and Builtins
 - 14.1. Job Control Commands
- 15. External Filters, Programs and Commands
 - 15.1. Basic Commands
 - 15.2. Complex Commands

- 15.3. Time / Date Commands
- 15.4. Text Processing Commands
- 15.5. File and Archiving Commands
- 15.6. Communications Commands
- 15.7. Terminal Control Commands
- 15.8. Math Commands
- 15.9. Miscellaneous Commands
- 16. System and Administrative Commands
 - 16.1. Analyzing a System Script
- Part 5. Advanced Topics
 - 17. Regular Expressions
 - 17.1. A Brief Introduction to Regular Expressions
 - 17.2. Globbing
 - 18. Here Documents
 - 18.1. Here Strings
 - 19. I/O Redirection
 - 19.1. <u>Using *exec*</u>
 - 19.2. Redirecting Code Blocks
 - 19.3. Applications
 - 20. Subshells
 - 21. Restricted Shells
 - 22. Process Substitution
 - 23. Functions
 - 23.1. Complex Functions and Function Complexities
 - 23.2. Local Variables
 - 23.3. Recursion Without Local Variables
 - 24. Aliases
 - 25. <u>List Constructs</u>
 - 26. Arrays
 - 27. /dev and /proc
 - 27.1. <u>/dev</u>
 - 27.2. /proc
 - 28. Of Zeros and Nulls
 - 29. Debugging
 - 30. Options
 - 31. Gotchas
 - 32. Scripting With Style
 - 32.1. <u>Unofficial Shell Scripting Stylesheet</u>
 - 33. Miscellany
 - 33.1. <u>Interactive and non-interactive shells and scripts</u>
 - 33.2. Operator Precedence
 - 33.3. Shell Wrappers
 - 33.4. <u>Tests and Comparisons: Alternatives</u>
 - 33.5. Recursion
 - 33.6. "Colorizing" Scripts
 - 33.7. Optimizations
 - 33.8. Assorted Tips
 - 33.9. Security Issues
 - 33.10. Portability Issues
 - 33.11. Shell Scripting Under Windows
 - 34. Bash, versions 2 and 3
 - 34.1. Bash, version 2
 - 34.2. Bash, version 3

- 35.1. Author's Note
- 35.2. About the Author
- 35.3. Where to Go For Help
- 35.4. Tools Used to Produce This Book
 - 35.4.1. <u>Hardware</u>
 - 35.4.2. Software and Printware
- 35.5. Credits
- 35.6. Disclaimer

Bibliography

- A. Contributed Scripts
- B. Reference Cards
- C. A Sed and Awk Micro-Primer
 - C.1. <u>Sed</u>
 - C.2. Awk
- D. Exit Codes With Special Meanings
- E. A Detailed Introduction to I/O and I/O Redirection
- F. Command-Line Options
 - F.1. Standard Command-Line Options
 - F.2. <u>Bash Command-Line Options</u>
- G. Important Files
- H. Important System Directories
- I. Localization
- J. <u>History Commands</u>
- K. A Sample .bashrc File
- L. Converting DOS Batch Files to Shell Scripts
- M. Exercises
 - M.1. Analyzing Scripts
 - M.2. Writing Scripts
- N. Revision History
- O. Mirror Sites
- P. To Do List
- Q. Copyright
- R. ASCII Table
- <u>Index</u>

List of Tables

- 14-1. Job identifiers
- 30-1. Bash options
- 33-1. Operator Precedence
- 33-2. Numbers representing colors in Escape Sequences
- B-1. Special Shell Variables
- B-2. TEST Operators: Binary Comparison
- B-3. TEST Operators: Files
- B-4. Parameter Substitution and Expansion
- B-5. String Operations
- B-6. Miscellaneous Constructs
- C-1. <u>Basic sed operators</u>
- C-2. Examples of sed operators
- D-1. Reserved Exit Codes
- L-1. <u>Batch file keywords / variables / operators, and their shell equivalents</u>
- L-2. DOS commands and their UNIX equivalents
- N-1. Revision History

List of Examples

- 2-1. cleanup: A script to clean up the log files in /var/log
- 2-2. cleanup: An improved clean-up script
- 2-3. *cleanup*: An enhanced and generalized version of above scripts.
- 3-1. Code blocks and I/O redirection
- 3-2. Saving the output of a code block to a file
- 3-3. Running a loop in the background
- 3-4. Backup of all files changed in last day
- 4-1. <u>Variable assignment and substitution</u>
- 4-2. Plain Variable Assignment
- 4-3. Variable Assignment, plain and fancy
- 4-4. <u>Integer or string?</u>
- 4-5. <u>Positional Parameters</u>
- 4-6. wh, whois domain name lookup
- 4-7. Using shift
- 5-1. Echoing Weird Variables
- 5-2. Escaped Characters
- 6-1. exit / exit status
- 6-2. Negating a condition using!
- 7-1. What is truth?
- 7-2. Equivalence of test, /usr/bin/test, [], and /usr/bin/[
- 7-3. Arithmetic Tests using (())
- 7-4. Testing for broken links
- 7-5. Arithmetic and string comparisons
- 7-6. Testing whether a string is *null*
- 7-7. *zmore*
- 8-1. Greatest common divisor
- 8-2. <u>Using Arithmetic Operations</u>
- 8-3. Compound Condition Tests Using && and ||
- 8-4. Representation of numerical constants
- 9-1. \$IFS and whitespace
- 9-2. Timed Input
- 9-3. Once more, timed input
- 9-4. Timed read
- 9-5. <u>Am I root?</u>
- 9-6. arglist: Listing arguments with \$* and \$@
- 9-7. Inconsistent \$* and \$@ behavior
- 9-8. \$* and \$@ when \$IFS is empty
- 9-9. <u>Underscore variable</u>
- 9-10. Inserting a blank line between paragraphs in a text file
- 9-11. Generating an 8-character "random" string
- 9-12. Converting graphic file formats, with filename change
- 9-13. Converting streaming audio files to ogg
- 9-14. Emulating getopt
- 9-15. Alternate ways of extracting substrings
- 9-16. <u>Using parameter substitution and error messages</u>
- 9-17. Parameter substitution and "usage" messages
- 9-18. Length of a variable
- 9-19. Pattern matching in parameter substitution
- 9-20. Renaming file extensions:
- 9-21. Using pattern matching to parse arbitrary strings
- 9-22. Matching patterns at prefix or suffix of string
- 9-23. <u>Using declare to type variables</u>
- 9-24. Indirect Variable References
- 9-25. Passing an indirect reference to awk

- 9-26. Generating random numbers
- 9-27. Picking a random card from a deck
- 9-28. Brownian Motion Simulation
- 9-29. Random between values
- 9-30. Rolling a single die with RANDOM
- 9-31. Reseeding RANDOM
- 9-32. Pseudorandom numbers, using awk
- 9-33. C-style manipulation of variables
- 10-1. Simple for loops
- 10-2. for loop with two parameters in each [list] element
- 10-3. Fileinfo: operating on a file list contained in a variable
- 10-4. Operating on files with a *for* loop
- 10-5. Missing in [list] in a for loop
- 10-6. Generating the [list] in a for loop with command substitution
- 10-7. A grep replacement for binary files
- 10-8. Listing all users on the system
- 10-9. Checking all the binaries in a directory for authorship
- 10-10. <u>Listing the *symbolic links*</u> in a directory
- 10-11. Symbolic links in a directory, saved to a file
- 10-12. A C-style for loop
- 10-13. <u>Using *efax* in batch mode</u>
- 10-14. Simple while loop
- 10-15. Another while loop
- 10-16. while loop with multiple conditions
- 10-17. C-style syntax in a while loop
- 10-18. *until* loop
- 10-19. Nested Loop
- 10-20. Effects of break and continue in a loop
- 10-21. Breaking out of multiple loop levels
- 10-22. Continuing at a higher loop level
- 10-23. <u>Using continue N in an actual task</u>
- 10-24. Using *case*
- 10-25. Creating menus using case
- 10-26. Using command substitution to generate the case variable
- 10-27. Simple string matching
- 10-28. Checking for alphabetic input
- 10-29. Creating menus using select
- 10-30. Creating menus using select in a function
- 11-1. Stupid script tricks
- 11-2. Generating a variable from a loop
- 11-3. Finding anagrams
- 14-1. A script that forks off multiple instances of itself
- 14-2. *printf* in action
- 14-3. Variable assignment, using read
- 14-4. What happens when read has no variable
- 14-5. Multi-line input to read
- 14-6. Detecting the arrow keys
- 14-7. <u>Using read with file redirection</u>
- 14-8. Problems reading from a pipe
- 14-9. Changing the current working directory
- 14-10. Letting let do arithmetic.
- 14-11. Showing the effect of eval
- 14-12. *Echoing* the *command-line parameters*
- 14-13. Forcing a log-off

- 14-14. <u>A version of *rot13*</u>
- 14-15. Using eval to force variable substitution in a Perl script
- 14-16. <u>Using set with positional parameters</u>
- 14-17. Reversing the positional parameters
- 14-18. Reassigning the positional parameters
- 14-19. "Unsetting" a variable
- 14-20. <u>Using export to pass a variable to an embedded awk script</u>
- 14-21. <u>Using getopts</u> to read the options/arguments passed to a script
- 14-22. "Including" a data file
- 14-23. A (useless) script that sources itself
- 14-24. Effects of exec
- 14-25. A script that exec's itself
- 14-26. Waiting for a process to finish before proceeding
- 14-27. A script that kills itself
- 15-1. Using ls to create a table of contents for burning a CDR disk
- 15-2. Hello or Good-bye
- 15-3. Badname, eliminate file names in current directory containing bad characters and whitespace.
- 15-4. Deleting a file by its *inode* number
- 15-5. <u>Logfile: Using xargs to monitor system log</u>
- 15-6. Copying files in current directory to another
- 15-7. Killing processes by name
- 15-8. Word frequency analysis using xargs
- 15-9. <u>Using *expr*</u>
- 15-10. <u>Using date</u>
- 15-11. Date calculations
- 15-12. Word Frequency Analysis
- 15-13. Which files are scripts?
- 15-14. Generating 10-digit random numbers
- 15-15. <u>Using tail to monitor the system log</u>
- 15-16. Printing out the From lines in stored e-mail messages
- 15-17. Emulating grep in a script
- 15-18. Looking up definitions in Webster's 1913 Dictionary
- 15-19. Checking words in a list for validity
- 15-20. toupper: Transforms a file to all uppercase.
- 15-21. lowercase: Changes all filenames in working directory to lowercase.
- 15-22. du: DOS to UNIX text file conversion.
- 15-23. rot13: ultra-weak encryption.
- 15-24. Generating "Crypto-Quote" Puzzles
- 15-25. Formatted file listing.
- 15-26. Using column to format a directory listing
- 15-27. nl: A self-numbering script.
- 15-28. *manyiew*: Viewing formatted manpages
- 15-29. <u>Using *cpio* to move a directory tree</u>
- 15-30. Unpacking an rpm archive
- 15-31. Stripping comments from C program files
- 15-32. Exploring /usr/X11R6/bin
- 15-33. An "improved" strings command
- 15-34. <u>Using *cmp* to compare two files within a script.</u>
- 15-35. basename and dirname
- 15-36. A script that copies itself in sections
- 15-37. Checking file integrity
- 15-38. <u>Uudecoding encoded files</u>
- 15-39. Finding out where to report a spammer
- 15-40. Analyzing a spam domain

- 15-41. Getting a stock quote
- 15-42. Updating FC4
- 15-43. <u>Using ssh</u>
- 15-44. A script that mails itself
- 15-45. Monthly Payment on a Mortgage
- 15-46. <u>Base Conversion</u>
- 15-47. <u>Invoking bc using a here document</u>
- 15-48. Calculating PI
- 15-49. Converting a decimal number to hexadecimal
- 15-50. Factoring
- 15-51. Calculating the hypotenuse of a triangle
- 15-52. <u>Using seq to generate loop arguments</u>
- 15-53. Letter Count"
- 15-54. Using *getopt* to parse command-line options
- 15-55. A script that copies itself
- 15-56. Exercising dd
- 15-57. Capturing Keystrokes
- 15-58. Securely deleting a file
- 15-59. Filename generator
- 15-60. Converting meters to miles
- 15-61. <u>Using *m4*</u>
- 16-1. Setting a new password
- 16-2. Setting an erase character
- 16-3. secret password: Turning off terminal echoing
- 16-4. <u>Keypress detection</u>
- 16-5. Checking a remote server for idental
- 16-6. *pidof* helps kill a process
- 16-7. Checking a CD image
- 16-8. Creating a filesystem in a file
- 16-9. Adding a new hard drive
- 16-10. Using *umask* to hide an output file from prying eyes
- 16-11. killall, from /etc/rc.d/init.d
- 18-1. broadcast: Sends message to everyone logged in
- 18-2. <u>dummyfile</u>: Creates a 2-line dummy file
- 18-3. Multi-line message using *cat*
- 18-4. Multi-line message, with tabs suppressed
- 18-5. Here document with parameter substitution
- 18-6. Upload a file pair to *Sunsite* incoming directory
- 18-7. Parameter substitution turned off
- 18-8. A script that generates another script
- 18-9. Here documents and functions
- 18-10. "Anonymous" Here Document
- 18-11. Commenting out a block of code
- 18-12. A self-documenting script
- 18-13. Prepending a line to a file
- 18-14. Parsing a mailbox
- 19-1. Redirecting stdin using exec
- 19-2. Redirecting stdout using exec
- 19-3. Redirecting both stdin and stdout in the same script with exec
- 19-4. Avoiding a subshell
- 19-5. Redirected while loop
- 19-6. Alternate form of redirected while loop
- 19-7. Redirected until loop
- 19-8. Redirected for loop

- 19-9. Redirected for loop (both stdin and stdout redirected)
- 19-10. Redirected if/then test
- 19-11. Data file names.data for above examples
- 19-12. Logging events
- 20-1. <u>Variable scope in a subshell</u>
- 20-2. <u>List User Profiles</u>
- 20-3. Running parallel processes in subshells
- 21-1. Running a script in restricted mode
- 23-1. Simple functions
- 23-2. Function Taking Parameters
- 23-3. Functions and command-line args passed to the script
- 23-4. Passing an indirect reference to a function
- 23-5. Dereferencing a parameter passed to a function
- 23-6. Again, dereferencing a parameter passed to a function
- 23-7. Maximum of two numbers
- 23-8. Converting numbers to Roman numerals

Part 1. Introduction

The shell is a command interpreter. More than just the insulating layer between the operating system kernel and the user, it's also a fairly powerful programming language. A shell program, called a *script*, is an easy-to-use tool for building applications by "gluing" together system calls, tools, utilities, and compiled binaries. Virtually the entire repertoire of UNIX commands, utilities, and tools is available for invocation by a shell script. If that were not enough, internal shell commands, such as testing and loop constructs, give additional power and flexibility to scripts. Shell scripts lend themselves exceptionally well to administrative system tasks and other routine repetitive jobs not requiring the bells and whistles of a full-blown tightly structured programming language.

Chapter 1. Why Shell Programming?

No programming language is perfect. There is not even a single best language; there are only languages well suited or perhaps poorly suited for particular purposes.

--Herbert Mayer

A working knowledge of shell scripting is essential to anyone wishing to become reasonably proficient at system administration, even if they do not anticipate ever having to actually write a script. Consider that as a Linux machine boots up, it executes the shell scripts in /etc/rc.d to restore the system configuration and set up services. A detailed understanding of these startup scripts is important for analyzing the behavior of a system, and possibly modifying it.

Writing shell scripts is not hard to learn, since the scripts can be built in bite-sized sections and there is only a fairly small set of shell-specific operators and options [1] to learn. The syntax is simple and straightforward, similar to that of invoking and chaining together utilities at the command line, and there are only a few "rules" to learn. Most short scripts work right the first time, and debugging even the longer ones is straightforward.

A shell script is a "quick and dirty" method of prototyping a complex application. Getting even a limited subset of the functionality to work in a shell script is often a useful first stage in project development. This way, the structure of the application can be tested and played with, and the major pitfalls found before proceeding to the final coding in C, C++, Java, or \underline{Perl} .

Shell scripting hearkens back to the classic UNIX philosophy of breaking complex projects into simpler subtasks, of chaining together components and utilities. Many consider this a better, or at least more esthetically pleasing approach to problem solving than using one of the new generation of high powered all-in-one languages, such as *Perl*, which attempt to be all things to all people, but at the cost of forcing you to alter your thinking processes to fit the tool.

According to <u>Herbert Mayer</u>, "a useful language needs arrays, pointers, and a generic mechanism for building data structures." By these criteria, shell scripting falls somewhat short of being "useful." Or, perhaps not.

When not to use shell scripts

- Resource-intensive tasks, especially where speed is a factor (sorting, hashing, recursion [2] ...)
- Procedures involving heavy-duty math operations, especially floating point arithmetic, arbitrary precision calculations, or complex numbers (use *C*++ or *FORTRAN* instead)
- Cross-platform portability required (use C or Java instead)
- Complex applications, where structured programming is a necessity (need type-checking of variables, function prototypes, etc.)
- Mission-critical applications upon which you are betting the ranch, or the future of the company
- Situations where security is important, where you need to guarantee the integrity of your system and protect against intrusion, cracking, and vandalism
- Project consists of subcomponents with interlocking dependencies
- Extensive file operations required (*Bash* is limited to serial file access, and that only in a particularly clumsy and inefficient line-by-line fashion)
- Need native support for multi-dimensional arrays
- Need data structures, such as linked lists or trees
- Need to generate or manipulate graphics or GUIs
- Need direct access to system hardware
- Need port or socket I/O
- Need to use libraries or interface with legacy code

• Proprietary, closed-source applications (shell scripts put the source code right out in the open for all the world to see)

If any of the above applies, consider a more powerful scripting language -- perhaps *Perl*, *Tcl*, *Python*, *Ruby* -- or possibly a high-level compiled language such as *C*, *C*++, or *Java*. Even then, prototyping the application as a shell script might still be a useful development step.

We will be using Bash, an acronym for "Bourne-Again shell" and a pun on Stephen Bourne's now classic *Bourne* shell. Bash has become a *de facto* standard for shell scripting on all flavors of UNIX. Most of the principles this book covers apply equally well to scripting with other shells, such as the *Korn Shell*, from which Bash derives some of its features, [3] and the *C Shell* and its variants. (Note that *C Shell* programming is not recommended due to certain inherent problems, as pointed out in an October, 1993 <u>Usenet post</u> by Tom Christiansen.)

What follows is a tutorial on shell scripting. It relies heavily on examples to illustrate various features of the shell. The example scripts work -- they've been tested, insofar as was possible -- and some of them are even useful in real life. The reader can play with the actual working code of the examples in the source archive (scriptname.sh or scriptname.bash), [4] give them execute permission (chmod u+rx scriptname), then run them to see what happens. Should the source archive not be available, then cut-and-paste from the HTML, pdf, or text rendered versions. Be aware that some of the scripts presented here introduce features before they are explained, and this may require the reader to temporarily skip ahead for enlightenment.

Unless otherwise noted, the author of this book wrote the example scripts that follow.

Notes

- [1] These are referred to as <u>builtins</u>, features internal to the shell.
- [2] Although <u>recursion</u> is possible in a shell <u>script</u>, it tends to be slow and its implementation is often an <u>ugly kludge</u>.
- [3] Many of the features of ksh88, and even a few from the updated ksh93 have been merged into Bash.
- [4] By convention, user-written shell scripts that are Bourne shell compliant generally take a name with a .sh extension. System scripts, such as those found in /etc/rc.d, do not conform to this nomenclature.

Chapter 2. Starting Off With a Sha-Bang

Shell programming is a 1950s juke box . . .

--Larry Wall

In the simplest case, a script is nothing more than a list of system commands stored in a file. At the very least, this saves the effort of retyping that particular sequence of commands each time it is invoked.

Example 2-1. cleanup: A script to clean up the log files in /var/log

```
1 # Cleanup
2 # Run as root, of course.
3
4 cd /var/log
5 cat /dev/null > messages
6 cat /dev/null > wtmp
7 echo "Logs cleaned up."
```

There is nothing unusual here, only a set of commands that could just as easily be invoked one by one from the command line on the console or in an *xterm*. The advantages of placing the commands in a script go beyond not having to retype them time and again. The script becomes a *tool*, and can easily be modified or customized for a particular application.

Example 2-2. cleanup: An improved clean-up script

```
1 #!/bin/bash
2 # Proper header for a Bash script.
3
4 # Cleanup, version 2
5
6 # Run as root, of course.
7 # Insert code here to print error message and exit if not root.
8
9 LOG_DIR=/var/log
10 # Variables are better than hard-coded values.
11 cd $LOG_DIR
12
13 cat /dev/null > messages
14 cat /dev/null > wtmp
15
16
17 echo "Logs cleaned up."
18
19 exit # The right and proper method of "exiting" from a script.
```

Now that's beginning to look like a real script. But we can go even farther . . .

Example 2-3. cleanup: An enhanced and generalized version of above scripts.

```
1 #!/bin/bash
2 # Cleanup, version 3
3
4 # Warning:
5 # ------
6 # This script uses quite a number of features that will be explained
```

```
7 #+ later on.
8 # By the time you've finished the first half of the book,
9 #+ there should be nothing mysterious about it.
10
11
12
13 LOG_DIR=/var/log
14 ROOT_UID=0 # Only users with $UID 0 have root privileges.
15 LINES=50
                # Default number of lines saved.
16 E_XCD=66 # Can't change directory?
17 E_NOTROOT=67 # Non-root exit error.
18
19
20 # Run as root, of course.
21 if [ "$UID" -ne "$ROOT_UID" ]
23
   echo "Must be root to run this script."
24
   exit $E NOTROOT
25 fi
26
27 if [ -n "$1" ]
28 # Test if command line argument present (non-empty).
29 then
30 lines=$1
31 else
32 lines=$LINES # Default, if not specified on command line.
34
35
36 # Stephane Chazelas suggests the following,
37 #+ as a better way of checking command line arguments,
38 #+ but this is still a bit advanced for this stage of the tutorial.
39 #
40 #
      E_WRONGARGS=65 # Non-numerical argument (bad arg format)
41 #
      case "$1" in
42 #
43 #
       "" ) lines=50;;
      *[!0-9]*) echo "Usage: `basename $0` file-to-cleanup"; exit $E_WRONGARGS;;
44 #
             ) lines=$1;;
45 #
      esac
46 #
47 #
48 #* Skip ahead to "Loops" chapter to decipher all this.
49
50
51 cd $LOG_DIR
53 if [ `pwd` != "$LOG_DIR" ] # or if [ "$PWD" != "$LOG_DIR" ]
54
                              # Not in /var/log?
55 then
56 echo "Can't change to $LOG_DIR."
57 exit $E_XCD
58 fi # Doublecheck if in right directory, before messing with log file.
59
60 # far more efficient is:
61 #
62 # cd /var/log || {
63 # echo "Cannot change to necessary directory." >&2
64 # exit $E_XCD;
65 # }
66
67
68
70 tail -n $lines messages > mesg.temp # Saves last section of message log file.
71 mv mesg.temp messages
                                    # Becomes new log directory.
72
```

```
73
74 # cat /dev/null > messages
75 #* No longer needed, as the above method is safer.
76
77 cat /dev/null > wtmp # ': > wtmp' and '> wtmp' have the same effect.
78 echo "Logs cleaned up."
79
80 exit 0
81 # A zero return value from the script upon exit
82 #+ indicates success to the shell.
```

Since you may not wish to wipe out the entire system log, this version of the script keeps the last section of the message log intact. You will constantly discover ways of refining previously written scripts for increased effectiveness.

The *sha-bang* (#!) at the head of a script tells your system that this file is a set of commands to be fed to the command interpreter indicated. The #! is actually a two-byte [1] *magic number*, a special marker that designates a file type, or in this case an executable shell script (type man magic for more details on this fascinating topic). Immediately following the *sha-bang* is a *path name*. This is the path to the program that interprets the commands in the script, whether it be a shell, a programming language, or a utility. This command interpreter then executes the commands in the script, starting at the top (line following the *sha-bang* line), ignoring comments. [2]

```
1 #!/bin/sh
2 #!/bin/bash
3 #!/usr/bin/perl
4 #!/usr/bin/tcl
5 #!/bin/sed -f
6 #!/usr/awk -f
```

Each of the above script header lines calls a different command interpreter, be it /bin/sh, the default shell (bash in a Linux system) or otherwise. [3] Using #!/bin/sh, the default Bourne shell in most commercial variants of UNIX, makes the script portable to non-Linux machines, though you sacrifice Bash-specific features. The script will, however, conform to the POSIX [4] sh standard.

Note that the path given at the "sha-bang" must be correct, otherwise an error message -- usually "Command not found" -- will be the only result of running the script.

#! can be omitted if the script consists only of a set of generic system commands, using no internal shell directives. The second example, above, requires the initial #!, since the variable assignment line, lines=50, uses a shell-specific construct. [5] Note again that #!/bin/sh invokes the default shell interpreter, which defaults to /bin/bash on a Linux machine.

This tutorial encourages a modular approach to constructing a script. Make note of and collect "boilerplate" code snippets that might be useful in future scripts. Eventually you can build quite an extensive library of nifty routines. As an example, the following script prolog tests whether the script has been invoked with the correct number of parameters.

Many times, you will write a script that carries out one particular task. The first script in this chapter is an example of this. Later, it might occur to you to generalize the script to do other, similar tasks. Replacing the literal ("hard-wired") constants by variables is a step in that direction, as is replacing repetitive code blocks by <u>functions</u>.

2.1. Invoking the script

Having written the script, you can invoke it by **sh scriptname**, [6] or alternatively **bash scriptname**. (Not recommended is using **sh <scriptname**, since this effectively disables reading from stdin within the script.) Much more convenient is to make the script itself directly executable with a chmod.

```
Either:

chmod 555 scriptname (gives everyone read/execute permission) [7]

or

chmod +rx scriptname (gives everyone read/execute permission)
```

"sha-bang" line, invoking the script calls the correct command interpreter to run it.

Having made the script executable, you may now test it by ./scriptname. [8] If it begins with a

chmod u+rx scriptname (gives only the script owner read/execute permission)

As a final step, after testing and debugging, you would likely want to move it to /usr/local/bin (as *root*, of course), to make the script available to yourself and all other users as a systemwide executable. The script could then be invoked by simply typing **scriptname** [ENTER] from the command line.

Notes

- [1] Some flavors of UNIX (those based on 4.2 BSD) allegedly take a four-byte magic number, requiring a blank after the ! -- #! /bin/sh. However, according to Sven Mascheck, this is probably a myth.
- [2] The #! line in a shell script will be the first thing the command interpreter (sh or bash) sees. Since this line begins with a #, it will be correctly interpreted as a comment when the command interpreter finally executes the script. The line has already served its purpose calling the command interpreter.

If, in fact, the script includes an extra #! line, then bash will interpret it as a comment.

```
1 #!/bin/bash
2
3 echo "Part 1 of script."
4 a=1
5
6 #!/bin/bash
7 # This does *not* launch a new script.
8
9 echo "Part 2 of script."
10 echo $a # Value of $a stays at 1.
```

[3] This allows some cute tricks.

```
1 #!/bin/rm
2 # Self-deleting script.
3
4 # Nothing much seems to happen when you run this... except that the file disappears.
5
6 WHATEVER=65
7
8 echo "This line will never print (betcha!)."
9
10 exit $WHATEVER # Doesn't matter. The script will not exit here.
11 # Try an echo $? after script termination.
12 # You'll get a 0, not a 65.
```

Also, try starting a README file with a #!/bin/more, and making it executable. The result is a self-listing documentation file. (A here document using cat is possibly a better alternative -- see Example 18-3).

- [4] Portable Operating System Interface, an attempt to standardize UNIX-like OSes. The POSIX specifications are listed on the Open Group site.
- [5] If *Bash* is your default shell, then the #! isn't necessary at the beginning of a script. However, if launching a script from a different shell, such as *tcsh*, then you *will* need the #!.
- [6] Caution: invoking a *Bash* script by **sh scriptname** turns off Bash-specific extensions, and the script may therefore fail to execute.
- [7] A script needs *read*, as well as execute permission for it to run, since the shell needs to be able to read it.
- [8] Why not simply invoke the script with scriptname? If the directory you are in (\$PWD) is where scriptname is located, why doesn't this work? This fails because, for security reasons, the current directory (./) is not by default included in a user's \$PATH\$. It is therefore necessary to explicitly invoke the script in the current directory with a ./scriptname.

2.2. Preliminary Exercises

- 1. System administrators often write scripts to automate common tasks. Give several instances where such scripts would be useful.
- 2. Write a script that upon invocation shows the <u>time and date</u>, <u>lists all logged-in users</u>, and gives the system <u>uptime</u>. The script then <u>saves this information</u> to a logfile.

Chapter 3. Special Characters

Special Characters Found In Scripts and Elsewhere

#

Comments. Lines beginning with a # (with the exception of #!) are comments and will not be executed.

```
1 # This line is a comment.
```

Comments may also occur following the end of a command.

```
1 echo "A comment will follow." # Comment here.
                               ^ Note whitespace before #
```

Comments may also follow whitespace at the beginning of a line.

```
# A tab precedes this comment.
```

1 A command may not follow a comment on the same line. There is no method of terminating the comment, in order for "live code" to begin on the same line. Use a new line for the next command.

(gradient of course, an escaped # in an echo statement does not begin a comment. Likewise, a # appears in certain parameter substitution constructs and in <u>numerical constant</u> expressions.

```
1 echo "The # here does not begin a comment."
2 echo 'The # here does not begin a comment.'
3 echo The \# here does not begin a comment.
4 echo The # here begins a comment.
6 echo ${PATH#*:} # Parameter substitution, not a comment.
7 echo $(( 2#101011 )) # Base conversion, not a comment.
9 # Thanks, S.C.
```

The standard <u>quoting</u> and <u>escape</u> characters (" '\) escape the #.

Certain pattern matching operations also use the #.

Command separator [semicolon]. Permits putting two or more commands on the same line.

```
1 echo hello; echo there
4 if [ -x "$filename" ]; then
                               # Note that "if" and "then" need separation.
                                # Why?
  echo "File $filename exists."; cp $filename $filename.bak
8 echo "File $filename not found."; touch $filename
9 fi; echo "File test complete."
```

Note that the ";" sometimes needs to be <u>escaped</u>.

Terminator in a <u>case</u> option [double semicolon].

```
1 case "$variable" in
2 abc) echo "\$variable = abc" ;;
3 xyz) echo "\$variable = xyz" ;;
4 esac
```

"dot" command [period]. Equivalent to source (see Example 14-22). This is a bash builtin.

"dot", as a component of a filename. When working with filenames, a dot is the prefix of a "hidden" file, a file that an <u>ls</u> will not normally show.

When considering directory names, a single dot represents the current working directory, and two dots denote the parent directory.

```
bash$ pwd
/home/bozo/projects

bash$ cd .
bash$ pwd
/home/bozo/projects

bash$ cd ..
bash$ pwd
/home/bozo/
```

The *dot* often appears as the destination (directory) of a file movement command.

```
bash$ cp /home/bozo/current_work/junk/* .
```

"dot" character match. When <u>matching characters</u>, as part of a <u>regular expression</u>, a "dot" matches a single character.

partial quoting [double quote]. "STRING" preserves (from interpretation) most of the special characters within STRING. See also Chapter 5.

<u>full quoting</u> [single quote]. 'STRING' preserves all special characters within STRING. This is a stronger form of quoting than using ". See also <u>Chapter 5</u>.

comma operator. The *comma operator* [1] links together a series of arithmetic operations. All are evaluated, but only the last one is returned.

```
1 let "t2 = ((a = 9, 15 / 3))" # Set "a = 2 9" and "t2 = 15 / 3"
```

escape [backslash]. A quoting mechanism for single characters.

١

\X "escapes" the character X. This has the effect of "quoting" X, equivalent to X'. The \ may be used to quote " and ', so they are expressed literally.

See <u>Chapter 5</u> for an in-depth explanation of escaped characters.

Filename path separator [forward slash]. Separates the components of a filename (as in /home/bozo/projects/Makefile).

This is also the division <u>arithmetic operator</u>.

command substitution. The **`command`** construct makes available the output of **command** for assignment to a variable. This is also known as <u>backquotes</u> or backticks.

null command [colon]. This is the shell equivalent of a "NOP" (no op, a do-nothing operation). It may be considered a synonym for the shell builtin <u>true</u>. The ":" command is itself a *Bash* <u>builtin</u>, and its <u>exit status</u> is "true" (0).

```
1 :
2 echo $? # 0
```

Endless loop:

```
1 while :
2 do
3    operation-1
4    operation-2
5    ...
6    operation-n
7 done
8
9 # Same as:
10 # while true
11 # do
12 # ...
13 # done
```

Placeholder in if/then test:

```
1 if condition
2 then: # Do nothing and branch ahead
3 else
4 take-some-action
5 fi
```

Provide a placeholder where a binary operation is expected, see Example 8-2 and default parameters.

```
1 : ${username=`whoami`}
2 # ${username=`whoami`}
3 # Gives an error without the leading :
unless "username" is a command or builtin...
```

Provide a placeholder where a command is expected in a <u>here document</u>. See <u>Example 18-10</u>.

Evaluate string of variables using parameter substitution (as in Example 9-16).

```
1 : ${HOSTNAME?} ${USER?} ${MAIL?}
2 # Prints error message
3 #+ if one or more of essential environmental variables not set.
```

Variable expansion / substring replacement.

In combination with the > <u>redirection operator</u>, truncates a file to zero length, without changing its permissions. If the file did not previously exist, creates it.

```
1 : > data.xxx  # File "data.xxx" now empty.
2
3 # Same effect as cat /dev/null >data.xxx
4 # However, this does not fork a new process, since ":" is a builtin.
See also <a href="Example 15-15">Example 15-15</a>.
```

In combination with the >> redirection operator, has no effect on a pre-existing target file (: >> target_file). If the file did not previously exist, creates it.

This applies to regular files, not pipes, symlinks, and certain special files.

May be used to begin a comment line, although this is not recommended. Using # for a comment turns off error checking for the remainder of that line, so almost anything may appear in a comment. However, this is not the case with:

```
1: This is a comment that generates an error, (if [$x -eq 3]).

The ":" also serves as a field separator, in /etc/passwd, and in the $\frac{\text{SPATH}}{2}$ variable.
```

```
bash$ echo $PATH
  /usr/local/bin:/usr/bin:/usr/X11R6/bin:/sbin:/usr/sbin:/usr/games
```

reverse (or negate) the sense of a test or exit status [bang]. The ! operator inverts the exit status of the command to which it is applied (see Example 6-2). It also inverts the meaning of a test operator. This can, for example, change the sense of equal (\equiv) to not-equal (\equiv). The ! operator is a Bash keyword.

In a different context, the ! also appears in indirect variable references.

In yet another context, from the *command line*, the ! invokes the Bash *history mechanism* (see Appendix J). Note that within a script, the history mechanism is disabled.

wild card [asterisk]. The * character serves as a "wild card" for filename expansion in globbing. By itself, it matches every filename in a given directory.

```
bash$ echo *
  abs-book.sgml add-drive.sh agram.sh alias.sh
```

The * also represents any number (or zero) characters in a <u>regular expression</u>.

arithmetic operator. In the context of arithmetic operations, the * denotes multiplication.

A double asterisk, **, is the exponentiation operator.

test operator. Within certain expressions, the ? indicates a test for a condition.

In a <u>double parentheses construct</u>, the ? can serve as an element of a C-style *trinary* operator, ? : .

!

*

*

?

```
9 # fi
```

In a parameter substitution expression, the ? tests whether a variable has been set.

wild card. The ? character serves as a single-character "wild card" for filename expansion in globbing, as well as representing one character in an extended regular expression.

\$

?

Variable substitution (contents of a variable).

```
1 var1=5
2 var2=23skidoo
3
4 echo $var1  # 5
5 echo $var2  # 23skidoo
```

A \$ prefixing a variable name indicates the *value* the variable holds.

\$

end-of-line. In a regular expression, a "\$" addresses the end of a line of text.

\${}

Parameter substitution.

\$*,\$@

positional parameters.

\$?

exit status variable. The <u>\$? variable</u> holds the <u>exit status</u> of a command, a <u>function</u>, or of the script itself.

\$\$

process ID variable. The \$\\$\ variable \text{ holds the } process ID [2] of the script in which it appears.

()

command group.

```
1 (a=hello; echo $a)
```

A listing of commands within parentheses starts a subshell.

Variables inside parentheses, within the subshell, are not visible to the rest of the script. The parent process, the script, <u>cannot read variables created in the child process</u>, the subshell.

```
1 a=123
2 ( a=321; )
3
4 echo "a = $a"  # a = 123
5 # "a" within parentheses acts like a local variable.
```

array initialization.

```
1 Array=(element1 element2 element3)
{xxx,yyy,zzz,...}
```

Brace expansion.

```
1 cat {file1,file2,file3} > combined_file
2 # Concatenates the files file1, file2, and file3 into combined_file.
3
4
5 cp file22.{txt,backup}
6 # Copies "file22.txt" to "file22.backup"
```

A command may act upon a comma-separated list of file specs within braces. [3] Filename expansion (globbing) applies to the file specs between the braces.

1 No spaces allowed within the braces *unless* the spaces are quoted or escaped.

```
echo {file1,file2}\ :{\ A," B",' C'}

file1 : A file1 : B file1 : C file2 : A file2 : B file2 :
C
```

{a..z} Extended Brace expansion.

```
1 echo {a..z} # a b c d e f g h i j k l m n o p q r s t u v w x y z
2 # Echoes characters between a and z.
3
4 echo {0..3} # 0 1 2 3
5 # Echoes characters between 0 and 3.
```

The $\{a...z\}$ extended brace expansion construction is a feature introduced in version 3 of Bash.

Block of code [curly brackets]. Also referred to as an *inline group*, this construct, in effect, creates an *anonymous function* (a function without a name). However, unlike in a "standard" <u>function</u>, the variables inside a code block remain visible to the remainder of the script.

```
1 a=123
2 { a=321; }
3 echo "a = $a"  # a = 321  (value inside code block)
4
5 # Thanks, S.C.
```

The code block enclosed in braces may have **I/O** redirected to and from it.

Example 3-1. Code blocks and I/O redirection

```
1 #!/bin/bash
 2 # Reading lines in /etc/fstab.
 4 File=/etc/fstab
 5
 6 {
 7 read line1
 8 read line2
9 } < $File
11 echo "First line in $File is:"
12 echo "$line1"
13 echo
14 echo "Second line in $File is:"
15 echo "$line2"
16
17 exit 0
18
19 # Now, how do you parse the separate fields of each line?
20 # Hint: use awk, or . . .
21 # . . . Hans-Joerg Diers suggests using the "set" Bash builtin.
```

{}

Example 3-2. Saving the output of a code block to a file

```
1 #!/bin/bash
 2 # rpm-check.sh
 4 # Queries an rpm file for description, listing,
 5 #+ and whether it can be installed.
 6 # Saves output to a file.
 7 #
 8 # This script illustrates using a code block.
10 SUCCESS=0
11 E_NOARGS=65
12
13 if [ -z "$1" ]
14 then
15 echo "Usage: `basename $0` rpm-file"
16 exit $E_NOARGS
17 fi
18
19 { # Begin code block.
20 echo
21 echo "Archive Description:"
22 rpm -qpi $1  # Query description.
23 echo
24 echo "Archive Listing:"
25 rpm -qpl $1 # Query listing.
    echo
26
    rpm -i --test $1 # Query whether rpm file can be installed.
27
28
    if [ "$?" -eq $SUCCESS ]
29
    then
30
     echo "$1 can be installed."
31
   else
32
     echo "$1 cannot be installed."
33
   fi
34
    echo
                     # End code block.
35 } > "$1.test"  # Redirects output of everything in block to file.
37 echo "Results of rpm test in file $1.test"
38
39 # See rpm man page for explanation of options.
40
41 exit 0
```

Unlike a command group within (parentheses), as above, a code block enclosed by {braces} will *not* normally launch a <u>subshell</u>. [4]

placeholder for text. Used after $\underline{\text{xargs}} = \underline{i}$ (*replace strings* option). The {} double curly brackets are a placeholder for output text.

pathname. Mostly used in <u>find</u> constructs. This is *not* a shell <u>builtin</u>.

{}

{}\;

The ";" ends the -exec option of a **find** command sequence. It needs to be escaped to protect it from interpretation by the shell.

```
[]
        test.
        <u>Test</u> expression between []. Note that [ is part of the shell builtin test (and a synonym for it), not a
        link to the external command /usr/bin/test.
[[]]
        test.
        Test expression between [[ ]]. This is a shell <u>keyword</u>.
        See the discussion on the [[ ... ]] construct.
[]
        array element.
        In the context of an <u>array</u>, brackets set off the numbering of each element of that array.
           1 Array[1]=slot_1
           2 echo ${Array[1]}
[]
        range of characters.
        As part of a <u>regular expression</u>, brackets delineate a <u>range of characters</u> to match.
(())
        integer expansion.
        Expand and evaluate integer expression between (( )).
        See the discussion on the (( ... )) construct.
> &> >& >> < <>
        redirection.
        scriptname >filename redirects the output of scriptname to file filename. Overwrite
        filename if it already exists.
        command &>filename redirects both the stdout and the stderr of command to filename.
        command >&2 redirects stdout of command to stderr.
        scriptname >>filename appends the output of scriptname to file filename. If
        filename does not already exist, it is created.
        [i] <> filename opens file filename for reading and writing, and assigns file descriptor i to it. If
        filename does not exist, it is created.
        process substitution.
        (command) >
        < (command)
        <u>In a different context</u>, the "<" and ">" characters act as <u>string comparison operators</u>.
```

<u>In yet another context</u>, the "<" and ">" characters act as <u>integer comparison operators</u>. See also <u>Example 15-9</u>.

<<

redirection used in a here document.

<<<

redirection used in a here string.

<,>

ASCII comparison.

```
1 veg1=carrots
2 veg2=tomatoes
3
4 if [[ "$veg1" < "$veg2" ]]
5 then
6 echo "Although $veg1 precede $veg2 in the dictionary,"
7 echo -n "this does not necessarily imply anything "
8 echo "about my culinary preferences."
9 else
10 echo "What kind of dictionary are you using, anyhow?"
11 fi</pre>
```

\<, \>

word boundary in a regular expression.

```
bash$ grep '\<the\>' textfile
```

I

pipe. Passes the output (stdout of a previous command to the input (stdin) of the next one, or to the shell. This is a method of chaining commands together.

```
1 echo ls -1 | sh
2 # Passes the output of "echo ls -1" to the shell,
3 #+ with the same result as a simple "ls -1".
4
5
6 cat *.lst | sort | uniq
7 # Merges and sorts all ".lst" files, then deletes duplicate lines.
```

A pipe, as a classic method of interprocess communication, sends the stdout of one <u>process</u> to the stdin of another. In a typical case, a command, such as <u>cat</u> or <u>echo</u>, pipes a stream of data to a *filter* (a command that transforms its input) for processing.

```
cat $filename1 $filename2 | grep $search word
```

For an interesting note on the complexity of using UNIX pipes, see the UNIX FAQ, Part 3.

The output of a command or commands may be piped to a script.

```
1 #!/bin/bash
2 # uppercase.sh : Changes input to uppercase.
3
4 tr 'a-z' 'A-Z'
5 # Letter ranges must be quoted
6 #+ to prevent filename generation from single-letter filenames.
7
8 exit 0
```

Now, let us pipe the output of **ls -l** to this script.

```
bash$ ls -l | ./uppercase.sh
-RW-RW-R-- 1 BOZO BOZO 109 APR 7 19:49 1.TXT
-RW-RW-R-- 1 BOZO BOZO 109 APR 14 16:48 2.TXT
```

>

Ш

&

The stdout of each process in a pipe must be read as the stdin of the next. If this is not the case, the data stream will block, and the pipe will not behave as expected.

```
1 cat file1 file2 | ls -l | sort
2 # The output from "cat file1 file2" disappears.
```

A pipe runs as a child process, and therefore cannot alter script variables.

```
1 variable="initial_value"
2 echo "new_value" | read variable
3 echo "variable = $variable"  # variable = initial_value
```

If one of the commands in the pipe aborts, this prematurely terminates execution of the pipe. Called a *broken pipe*, this condition sends a *SIGPIPE* signal.

force redirection (even if the noclobber option is set). This will forcibly overwrite an existing file.

OR logical operator. In a <u>test construct</u>, the || operator causes a return of 0 (success) if *either* of the linked test conditions is true.

Run job in background. A command followed by an & will run in the background.

```
bash$ sleep 10 &
 [1] 850
 [1]+ Done
                              sleep 10
```

Within a script, commands and even <u>loops</u> may run in the background.

Example 3-3. Running a loop in the background

```
1 #!/bin/bash
2 # background-loop.sh
4 for i in 1 2 3 4 5 6 7 8 9 10 # First loop.
6 echo -n "$i "
7 done & # Run this loop in background.
8 # Will sometimes execute after second loop.
10 echo # This 'echo' sometimes will not display.
11
12 for i in 11 12 13 14 15 16 17 18 19 20 # Second loop.
14 echo -n "$i "
15 done
16
17 echo # This 'echo' sometimes will not display.
18
20
21 # The expected output from the script:
22 # 1 2 3 4 5 6 7 8 9 10
23 # 11 12 13 14 15 16 17 18 19 20
25 # Sometimes, though, you get:
26 # 11 12 13 14 15 16 17 18 19 20
27 # 1 2 3 4 5 6 7 8 9 10 bozo $
28 # (The second 'echo' doesn't execute. Why?)
```

```
29
30 # Occasionally also:
31 # 1 2 3 4 5 6 7 8 9 10 11 12 13 14 15 16 17 18 19 20
32 # (The first 'echo' doesn't execute. Why?)
34 # Very rarely something like:
35 # 11 12 13 1 2 3 4 5 6 7 8 9 10 14 15 16 17 18 19 20
36 # The foreground loop preempts the background one.
37
38 exit 0
39
40 # Nasimuddin Ansari suggests adding sleep 1
41 #+ after the echo -n "$i" in lines 6 and 14,
42 #+ for some real fun.
```

1 A command run in the background within a script may cause the script to hang, waiting for a keystroke. Fortunately, there is a <u>remedy</u> for this.

&&

AND logical operator. In a <u>test construct</u>, the && operator causes a return of 0 (success) only if *both* the linked test conditions are true.

option, prefix. Option flag for a command or filter. Prefix for an operator. Prefix for a <u>default</u> parameter in parameter substitution.

```
COMMAND -[Option1][Option2][...]
```

ls -al

sort -dfu \$filename

```
1 if [ $file1 -ot $file2 ]
  2 then # ^
  3 echo "File $file1 is older than $file2."
  6 if [ "$a" -eq "$b" ]
  7 then
  8 echo "$a is equal to $b."
 9 fi
 10
 11 if [ "$c" -eq 24 -a "$d" -eq 47 ]
 13 echo "$c equals 24 and $d equals 47."
 14 fi
 15
 16
 17 param2=${param1:-$DEFAULTVAL}
18 #
```

The *double-dash* — prefixes *long* (verbatim) options to commands.

sort --ignore-leading-blanks

Used with a <u>Bash builtin</u>, it means the *end of options* to that particular command.

(i) This provides a handy means of removing files whose names begin with a dash.

```
bash$ ls -l
  -rw-r--r- 1 bozo bozo 0 Nov 25 12:29 -badname

bash$ rm -- -badname

bash$ ls -l
  total 0
```

The double-dash is also used in conjunction with set.

```
set -- $variable (as in Example 14-18)
```

redirection from/to stdin or stdout [dash].

```
bash$ cat -
abc
abc
...
Ct1-D
```

As expected, **cat** - echoes stdin, in this case keyboarded user input, to stdout. But, does I/O redirection using - have real-world applications?

```
1 (cd /source/directory && tar cf - . ) | (cd /dest/directory && tar xpvf -)
 2 # Move entire file tree from one directory to another
 3 # [courtesy Alan Cox <a.cox@swansea.ac.uk>, with a minor change]
 5 # 1) cd /source/directory
 6 # Source directory, where the files to be moved are.
 7 # 2) &&
 8 # "And-list": if the 'cd' operation successful,
9 # then execute the next command.
10 # 3) tar cf - .
11 # The 'c' option 'tar' archiving command creates a new archive,
12 # the 'f' (file) option, followed by '-' designates the target file
13 # as stdout, and do it in current directory tree ('.').
14 # 4) |
15 # Piped to ...
16 # 5) ( ... )
17 #
     a subshell
18 # 6) cd /dest/directory
19 # Change to the destination directory.
20 # 7) &&
     "And-list", as above
21 #
22 # 8) tar xpvf -
23 # Unarchive ('x'), preserve ownership and file permissions ('p'),
24 \# and send verbose messages to stdout ('v'),
25 #
     reading data from stdin ('f' followed by '-').
27 #
     Note that 'x' is a command, and 'p', 'v', 'f' are options.
28 #
29 # Whew!
30
31
33 # More elegant than, but equivalent to:
34 # cd source/directory
35 # tar cf - . | (cd ../dest/directory; tar xpvf -)
37 # Also having same effect:
38 # cp -a /source/directory/* /dest/directory
        Or:
39 #
```

```
40 # cp -a /source/directory/* /source/directory/.[^.]* /dest/directory
41 # If there are hidden files in /source/directory.
```

```
1 bunzip2 -c linux-2.6.16.tar.bz2 | tar xvf -
2 # --uncompress tar file-- | --then pass it to "tar"--
3 # If "tar" has not been patched to handle "bunzip2",
4 #+ this needs to be done in two discrete steps, using a pipe.
5 # The purpose of the exercise is to unarchive "bzipped" kernel source.
```

Note that in this context the "-" is not itself a Bash operator, but rather an option recognized by certain UNIX utilities that write to stdout, such as tar, cat, etc.

```
bash$ echo "whatever" | cat -
whatever
```

Where a filename is expected, – redirects output to stdout (sometimes seen with tar cf), or accepts input from stdin, rather than from a file. This is a method of using a file-oriented utility as a filter in a pipe.

```
bash$ file
Usage: file [-bciknvzL] [-f namefile] [-m magicfiles] file...
```

By itself on the command line, <u>file</u> fails with an error message.

Add a "-" for a more useful result. This causes the shell to await user input.

```
bash$ file -
abc
standard input: ASCII text

bash$ file -
#!/bin/bash
standard input: Bourne-Again shell script text executable
```

Now the command accepts input from stdin and analyzes it.

The "-" can be used to pipe stdout to other commands. This permits such stunts as prepending lines to a file.

Using <u>diff</u> to compare a file with a *section* of another:

```
grep Linux file1 | diff file2 -
```

Finally, a real-world example using – with <u>tar</u>.

Example 3-4. Backup of all files changed in last day

```
1 #!/bin/bash
2
3 # Backs up all files in current directory modified within last 24 hours
4 #+ in a "tarball" (tarred and gzipped file).
5
6 BACKUPFILE=backup-$(date +%m-%d-%Y)
7 # Embeds date in backup filename.
8 # Thanks, Joshua Tschida, for the idea.
9 archive=${1:-$BACKUPFILE}
10 # If no backup-archive filename specified on command line,
11 #+ it will default to "backup-MM-DD-YYYY.tar.gz."
```

```
12
13 tar cvf - `find . -mtime -1 -type f -print` > $archive.tar
14 gzip $archive.tar
15 echo "Directory $PWD backed up in archive file \"$archive.tar.gz\"."
17
18 # Stephane Chazelas points out that the above code will fail
19 #+ if there are too many files found
20 #+ or if any filenames contain blank characters.
22 # He suggests the following alternatives:
23 # -
     find . -mtime -1 -type f -print0 | xargs -0 tar rvf "$archive.tar"
       using the GNU version of "find".
25 #
28 #
     find . -mtime -1 -type f -exec tar rvf "$archive.tar" '{}' \;
      portable to other UNIX flavors, but much slower.
31
32
33 exit 0
```

1 Filenames beginning with "-" may cause problems when coupled with the "-" redirection operator. A script should check for this and add an appropriate prefix to such filenames, for example . / -FILENAME, \$PWD/-FILENAME, or \$PATHNAME/-FILENAME.

If the value of a variable begins with a –, this may likewise create problems.

```
1 var="-n"
2 echo $var
3 \# Has the effect of "echo -n", and outputs nothing.
```

previous working directory. A cd - command changes to the previous working directory. This uses the \$OLDPWD environmental variable.

1 Do not confuse the "-" used in this sense with the "-" redirection operator just discussed. The interpretation of the "-" depends on the context in which it appears.

Minus. Minus sign in an <u>arithmetic operation</u>.

Equals. Assignment operator

```
1 a=28
2 echo $a
           # 28
```

In a <u>different context</u>, the "=" is a <u>string comparison</u> operator.

Plus. Addition <u>arithmetic operator</u>.

In a <u>different context</u>, the + is a <u>Regular Expression</u> operator.

Option. Option flag for a command or filter.

Certain commands and <u>builtins</u> use the + to enable certain options and the - to disable them. In <u>parameter substitution</u>, the + prefixes an <u>alternate value</u> that a variable expands to.

modulo. Modulo (remainder of a division) <u>arithmetic operation</u>.

+

+

In a <u>different context</u>, the % is a <u>pattern matching</u> operator.

home directory [tilde]. This corresponds to the <u>\$HOME</u> internal variable. ~bozo is bozo's home directory, and **ls ~bozo** lists the contents of it. ~/ is the current user's home directory, and **ls ~/** lists the contents of it.

```
bash$ echo ~bozo

/home/bozo

bash$ echo ~
/home/bozo

bash$ echo ~/
/home/bozo/

bash$ echo ~:
/home/bozo:

bash$ echo ~nonexistent-user
~nonexistent-user
```

~+

current working directory. This corresponds to the <u>\$PWD</u> internal variable.

--

previous working directory. This corresponds to the <u>\$OLDPWD</u> internal variable.

=~

Λ

<u>regular expression match</u>. This operator was introduced with <u>version 3</u> of Bash.

beginning-of-line. In a <u>regular expression</u>, a "^" addresses the beginning of a line of text. Control Characters

change the behavior of the terminal or text display. A control character is a **CONTROL** + **key** combination (pressed simultaneously). A control character may also be written in *octal* or *hexadecimal* notation, following an *escape*.

Control characters are not normally useful inside a script.

```
◇ Ct1-B

Backspace (nondestructive).

◇
Ct1-C

Break. Terminate a foreground job.

◇
Ct1-D

Log out from a shell (similar to exit).

"EOF" (end of file). This also terminates input from stdin.
```

When typing text on the console or in an *xterm* window, Ctl-D erases the character under the cursor. When there are no characters present, Ctl-D logs out of the session, as expected. In an xterm window, this has the effect of closing the window.

♦ Ctl-G

"BEL" (beep). On some old-time teletype terminals, this would actually ring a bell.

"Rubout" (destructive backspace). Erases characters the cursor backs over while backspacing.

```
1 #!/bin/bash
 2 # Embedding Ctl-H in a string.
4 a="^H^H"
                             # Two Ctl-H's -- backspaces
                            # ctl-V ctl-H, using vi/vim
6 echo "abcdef"
                            # abcdef
7 echo
8 echo -n "abcdef$a"  # abcd f
9 # Space at end ^ ^
                              ^ Backspaces twice.
10 echo
11 echo -n "abcdef$a" # abcdef
                            ^ Doesn't backspace (why?).
12 # No space at end
13
                            # Results may not be quite as expected.
14 echo; echo
15
16 # Constantin Hagemeier suggests trying:
17 # a=$'\010\010'
18 # a=$'\b\b'
19 \# a=\$'\x08\x08'
20 # But, this does not change the results.
```

♦ Ctl-I

Horizontal tab.

♦ Ctl-J

Newline (line feed). In a script, may also be expressed in octal notation -- '\012' or in hexadecimal -- '\x0a'.

♦ Ct.1-K

Vertical tab.

When typing text on the console or in an *xterm* window, Ctl-K erases from the character under the cursor to end of line. Within a script, Ctl-K may behave differently, as in Lee Lee Maschmeyer's example, below.

♦ Ctl-L

Formfeed (clear the terminal screen). In a terminal, this has the same effect as the <u>clear</u> command. When sent to a printer, a **Ctl-L** causes an advance to end of the paper sheet.

Ctl-M

 $\langle \rangle$

Carriage return.

```
1 #!/bin/bash
2 # Thank you, Lee Maschmeyer, for this example.
3
4 read -n 1 -s -p \
5 $'Control-M leaves cursor at beginning of this line. Press Enter. \x0d'
6 # Of course, '0d' is the hex equivalent of Control-M.
7 echo >&2 # The '-s' makes anything typed silent,
8 #+ so it is necessary to go to new line explicitly.
9
10 read -n 1 -s -p $'Control-J leaves cursor on next line. \x0a'
11 # '0a' is the hex equivalent of Control-J, linefeed.
12 echo >&2
13
```

```
14 ###
15
16 read -n 1 -s -p $'And Control-K\x0bgoes straight down.'
17 echo >&2 # Control-K is vertical tab.
19 # A better example of the effect of a vertical tab is:
21 var=$'\x0aThis is the bottom line\x0bThis is the top line\x0a'
22 echo "$var"
23 # This works the same way as the above example. However:
24 echo "$var" | col
25 # This causes the right end of the line to be higher than the left end.
26 \# It also explains why we started and ended with a line feed --
27 #+ to avoid a garbled screen.
29 # As Lee Maschmeyer explains:
30 #
31 # In the [first vertical tab example] . . . the vertical tab
32 #+ makes the printing go straight down without a carriage return.
33 # This is true only on devices, such as the Linux console,
34 #+ that can't go "backward."
35 # The real purpose of VT is to go straight UP, not down.
36 # It can be used to print superscripts on a printer.
37 \# The col utility can be used to emulate the proper behavior of VT.
39 exit 0
```

♦ Ctl-O

Resume (XON).

This resumes stdin in a terminal.

♦ Ctl-s

Suspend (XOFF).

This freezes stdin in a terminal. (Use Ctl-Q to restore input.)

♦ Ct.1-U

Erase a line of input, from the cursor backward to beginning of line. In some settings, Ctl-U erases the entire line of input, *regardless of cursor position*.

```
♦ Ctl-V
```

When inputting text, Ctl-V permits inserting control characters. For example, the following two are equivalent:

```
1 echo -e '\x0a'
2 echo <Ctl-V><Ctl-J>
```

Ctl-V is primarily useful from within a text editor.

♦ Ctl-W

When typing text on the console or in an xterm window, Ctl-W erases from the character under the cursor backwards to the first instance of whitespace. In some settings, Ctl-W erases backwards to first non-alphanumeric character.

♦ Ctl-Y

Pastes back text previously erased (with Ctl-K or Ctl-U).

♦ Ctl-Z

Pause a foreground job.

Whitespace

functions as a separator, separating commands or variables. Whitespace consists of either *spaces*, *tabs*, *blank lines*, or any combination thereof. [5] In some contexts, such as <u>variable assignment</u>, whitespace is not permitted, and results in a syntax error.

Blank lines have no effect on the action of a script, and are therefore useful for visually separating functional sections.

<u>\$IFS</u>, the special variable separating fields of input to certain commands, defaults to whitespace.

To preserve whitespace within a string or in a variable, use <u>quoting</u>.

Notes

- An *operator* is an agent that carries out an *operation*. Some examples are the common <u>arithmetic operators</u>, + * /. In Bash, there is some overlap between the concepts of *operator* and <u>keyword</u>.
- A *PID*, or *process ID*, is a number assigned to a running process. The *PID*s of running processes may be viewed with a <u>ps</u> command.

Definition: A process is an executing program, sometimes referred to as a job.

- [3] The shell does the *brace expansion*. The command itself acts upon the *result* of the expansion.
- [4] Exception: a code block in braces as part of a pipe may run as a <u>subshell</u>.

```
1 ls | { read firstline; read secondline; }
2 # Error. The code block in braces runs as a subshell,
3 #+ so the output of "ls" cannot be passed to variables within the block.
4 echo "First line is $firstline; second line is $secondline" # Will not work.
5
6 # Thanks, S.C.
```

[5] A linefeed ("newline") is also a whitespace character. This explains why a *blank line*, consisting only of a linefeed, is considered whitespace.

Parameters

Advanced Bash-Scripting Guide: An in-depth exploration of the art of shell scripting

<u>Prev</u> <u>Next</u>

Chapter 4. Introduction to Variables and Parameters

Variables are how programming and scripting languages represent data. A variable is nothing more than a *label*, a name assigned to a location or set of locations in computer memory holding an item of data.

Variables appear in arithmetic operations and manipulation of quantities, and in string parsing.

4.1. Variable Substitution

The *name* of a variable is a placeholder for its *value*, the data it holds. Referencing its value is called *variable substitution*.

\$

Let us carefully distinguish between the *name* of a variable and its *value*. If **variable1** is the name of a variable, then **\$variable1** is a reference to its *value*, the data item it contains. [1]

```
bash$ variable=23

bash$ echo variable
variable

bash$ echo $variable
23
```

The only time a variable appears "naked" -- without the \$ prefix -- is when declared or assigned, when *unset*, when <u>exported</u>, or in the special case of a variable representing a <u>signal</u> (see <u>Example 29-5</u>). Assignment may be with an = (as in var1=27), in a <u>read</u> statement, and at the head of a loop (for var2 in 1 2 3).

Enclosing a referenced value in *double quotes* (" ") does not interfere with variable substitution. This is called *partial quoting*, sometimes referred to as "weak quoting." Using single quotes (' ') causes the variable name to be used literally, and no substitution will take place. This is *full quoting*, sometimes referred to as "strong quoting." See <u>Chapter 5</u> for a detailed discussion.

Note that **\$variable** is actually a simplified alternate form of **\${variable}**. In contexts where the **\$variable** syntax causes an error, the longer form may work (see <u>Section 9.3</u>, below).

Example 4-1. Variable assignment and substitution

```
1 #!/bin/bash
 2 \# ex9.sh
 4 # Variables: assignment and substitution
 6 a=375
7 hello=$a
10 # No space permitted on either side of = sign when initializing variables.
11 # What happens if there is a space?
12
13 # "VARIABLE =value"
14 #
15 #% Script tries to run "VARIABLE" command with one argument, "=value".
16
17 # "VARIABLE= value"
18 #
19 #% Script tries to run "value" command with
20 #+ the environmental variable "VARIABLE" set to "".
22
23
24 echo hello # hello
```

```
25 # Not a variable reference, just the string "hello" . . .
27 echo $hello # 375
28 # ^ This *is* a variable reference.
29 echo ${hello} # 375
30 # Also a variable reference, as above.
31
32 # Quoting . . .
33 echo "$hello" # 375
34 echo "${hello}" # 375
3.5
36 echo
37
38 hello="A B C D"
39 echo $hello # A B C D
40 echo "$hello" # A B C D
41 # As you see, echo $hello and echo "$hello" give different results.
42 # Why?
44 # Quoting a variable preserves whitespace.
46
47 echo
48
49 echo '$hello' # $hello
51 # Variable referencing disabled (escaped) by single quotes,
52 #+ which causes the "$" to be interpreted literally.
54 # Notice the effect of different types of quoting.
55
56
57 hello=  # Setting it to a null value.
58 echo "\$hello (null value) = $hello"
59 \ \# Note that setting a variable to a null value is not the same as
60 #+ unsetting it, although the end result is the same (see below).
62 # -----
64 # It is permissible to set multiple variables on the same line,
65 #+ if separated by white space.
66 # Caution, this may reduce legibility, and may not be portable.
68 var1=21 var2=22 var3=$V3
69 echo
70 echo "var1=$var1 var2=$var2 var3=$var3"
72 # May cause problems with older versions of "sh" . . .
74 # -----
75
76 echo; echo
77
78 numbers="one two three"
79 # ^ ^
80 other_numbers="1 2 3"
81 #
82 # If there is whitespace embedded within a variable,
83 #+ then quotes are necessary.
84 # other_numbers=1 2 3
                                    # Gives an error message.
85 echo "numbers = $numbers"
86 echo "other_numbers = $other_numbers"  # other_numbers = 1 2 3
87 # Escaping the whitespace also works.
90
```

```
91 echo "$mixed_bag"
                              # 2 --- Whatever
 92
 93 echo; echo
 94
 95 echo "uninitialized_variable = $uninitialized_variable"
 96 # Uninitialized variable has null value (no value at all!).
 97 uninitialized_variable= # Declaring, but not initializing it --
                              #+ same as setting it to a null value, as above.
 99 echo "uninitialized_variable = $uninitialized_variable"
                              # It still has a null value.
100
101
102 uninitialized_variable=23
                                    # Set it.
103 unset uninitialized_variable # Unset it.
104 echo "uninitialized variable = $uninitialized variable"
105
                                    # It still has a null value.
106 echo
107
108 exit 0
```

An uninitialized variable has a "null" value - no assigned value at all (not zero!). Using a variable before assigning a value to it will usually cause problems.

It is nevertheless possible to perform arithmetic operations on an uninitialized variable.

See also Example 14-23.

Notes

[1] Technically, the *name* of a variable, VARIABLE, is called an *lvalue*, meaning that it appears on the *left* side of an assignment statment, as in *VARIABLE*=23. A variable's *value* is an *rvalue*, meaning that it appears on the *right* side of an assignment statement, as in *VAR2*=\$*VARIABLE*.

PrevHomeNextSpecial CharactersUpVariable Assignment

Advanced Bash-Scripting Guide: An in-depth exploration of the art of shell scripting

<u>Prev</u> Chapter 4. Introduction to Variables and Parameters

<u>Next</u>

4.2. Variable Assignment

the assignment operator (no space before and after)

1 Do not confuse this with \equiv and $\underline{-eq}$, which test, rather than assign!

Note that = can be either an assignment or a test operator, depending on context.

Example 4-2. Plain Variable Assignment

```
1 #!/bin/bash
 2 # Naked variables
 3
4 echo
6 # When is a variable "naked", i.e., lacking the '$' in front?
7 # When it is being assigned, rather than referenced.
9 # Assignment
10 a=879
11 echo "The value of \"a\" is $a."
13 # Assignment using 'let'
14 let a=16+5
15 echo "The value of \"a\" is now $a."
16
17 echo
18
19 # In a 'for' loop (really, a type of disguised assignment):
20 echo -n "Values of \"a\" in the loop are: "
21 for a in 7 8 9 11
23 echo -n "$a "
24 done
25
26 echo
27 echo
29 # In a 'read' statement (also a type of assignment):
30 echo -n "Enter \"a\" "
31 read a
32 echo "The value of \"a\" is now $a."
33
34 echo
35
36 exit 0
```

Example 4-3. Variable Assignment, plain and fancy

```
1 #!/bin/bash
3 a=23
                     # Simple case
4 echo $a
5 b=$a
6 echo $b
```

```
8 # Now, getting a little bit fancier (command substitution).
10 a='echo Hello!' # Assigns result of 'echo' command to 'a'
11 echo $a
12 # Note that including an exclamation mark (!) within a
13 #+ command substitution construct #+ will not work from the command line,
14 #+ since this triggers the Bash "history mechanism."
15 # Inside a script, however, the history functions are disabled.
16
17 a=`ls -l`
                     # Assigns result of 'ls -l' command to 'a'
                    # Unquoted, however, removes tabs and newlines.
18 echo $a
19 echo
20 echo "$a"
                    # The quoted variable preserves whitespace.
                     # (See the chapter on "Quoting.")
21
22
23 exit 0
```

Variable assignment using the \$(...) mechanism (a newer method than <u>backquotes</u>). This is actually a form of command substitution.

```
1 # From /etc/rc.d/rc.local
2 R=$(cat /etc/redhat-release)
3 arch=$(uname -m)
```

PrevHomeNextIntroduction to Variables andUpBash Variables Are Untyped

Introduction to Variables and Parameters

Advanced Bash-Scripting Guide: An in-depth exploration of the art of shell scripting

<u>Prev</u> Chapter 4. Introduction to Variables and Parameters <u>Next</u>

4.3. Bash Variables Are Untyped

Unlike many other programming languages, Bash does not segregate its variables by "type". Essentially, Bash variables are character strings, but, depending on context, Bash permits integer operations and comparisons on variables. The determining factor is whether the value of a variable contains only digits.

Example 4-4. Integer or string?

```
1 #!/bin/bash
  2 # int-or-string.sh: Integer or string?
 4 a=2334
                           # Integer.
 5 let "a += 1"
  6 echo "a = $a "
                           \# a = 2335
                           # Integer, still.
10 b=\$\{a/23/BB\}
                           # Substitute "BB" for "23".
                      # This
# b = BB35
# Declaring
                          # This transforms $b into a string.
11
11
12 echo "b = $b"
13 declare -i b
                          # Declaring it an integer doesn't help.
14 echo "b = $b"
                           \# b = BB35
16 let "b += 1"
                          # BB35 + 1 =
17 echo "b = $b"
                          \# b = 1
18 echo
20 c=BB34
21 echo "c = c" # c = BB34
22 d=cBB/23} # Substitute "23" for "BB".
                           # This makes $d an integer.
23
24 echo "d = $d"
                          \# d = 2334
25 let "d += 1"
                           # 2334 + 1 =
26 echo "d = $d"
                          \# d = 2335
 27 echo
 29 # What about null variables?
 31 echo "e = $e"
                          # e =
32 let "e += 1"
                           # Arithmetic operations allowed on a null variable?
33 echo "e = $e"
                          # e = 1
                           # Null variable transformed into an integer.
34 echo
35
36 # What about undeclared variables?
37 echo "f = f" # f =
38 let "f += 1"
                           # Arithmetic operations allowed?
39 echo "f = $f"
                          # f = 1
                           # Undeclared variable transformed into an integer.
40 echo
42
43
44 # Variables in Bash are essentially untyped.
45
46 exit 0
```

Untyped variables are both a blessing and a curse. They permit more flexibility in scripting (enough rope to hang yourself!) and make it easier to grind out lines of code. However, they permit errors to creep in and encourage sloppy programming habits.

The burden is on the programmer to keep track of what type the script variables are. Bash will not do it for you.

PrevHomeNextVariable AssignmentUpSpecial Variable TypesAdvanced Bash-Scripting Guide: An in-depth exploration of the art of shell scriptingPrevChapter 4. Introduction to Variables and ParametersNext

4.4. Special Variable Types

local variables

variables visible only within a code block or function (see also local variables in functions) environmental variables

variables that affect the behavior of the shell and user interface

In a more general context, each <u>process</u> has an "environment", that is, a group of variables that hold information that the process may reference. In this sense, the shell behaves like any other process.

Every time a shell starts, it creates shell variables that correspond to its own environmental variables. Updating or adding new environmental variables causes the shell to update its environment, and all the shell's child processes (the commands it executes) inherit this environment.

1 The space allotted to the environment is limited. Creating too many environmental variables or ones that use up excessive space may cause problems.

```
bash$ eval "`seq 10000 | sed -e 's/.*/export var&=ZZZZZZZZZZZZZZZZZ/'`"
 bash$ du
 bash: /usr/bin/du: Argument list too long
```

(Thank you, Stéphane Chazelas for the clarification, and for providing the above example.)

If a script sets environmental variables, they need to be "exported", that is, reported to the environment local to the script. This is the function of the export command.

A script can **export** variables only to child <u>processes</u>, that is, only to commands or processes which that particular script initiates. A script invoked from the command line cannot export variables back to the command line environment. Child processes cannot export variables back to the parent processes that spawned them.

Definition: A *child process* is a subprocess launched by another process, its *parent*.

```
positional parameters
```

arguments passed to the script from the command line: \$0, \$1, \$2, \$3...

\$0 is the name of the script itself, \$1 is the first argument, \$2 the second, \$3 the third, and so forth. After \$9, the arguments must be enclosed in brackets, for example, \$\{10\}, \$\{11\}, \$\{12\}.

The special variables \$* and \$@ denote all the positional parameters.

Example 4-5. Positional Parameters

```
1 #!/bin/bash
3 # Call this script with at least 10 parameters, for example
4 # ./scriptname 1 2 3 4 5 6 7 8 9 10
5 MINPARAMS=10
7 echo
```

```
9 echo "The name of this script is \"$0\"."
10 # Adds ./ for current directory
11 echo "The name of this script is \"`basename $0`\"."
12 # Strips out path name info (see 'basename')
14 echo
15
16 if [ -n "$1" ]
                            # Tested variable is quoted.
17 then
18 echo "Parameter #1 is $1" # Need quotes to escape #
19 fi
2.0
21 if [ -n "$2" ]
22 then
23 echo "Parameter #2 is $2"
24 fi
26 if [ -n "$3" ]
27 then
28 echo "Parameter #3 is $3"
29 fi
30
31 # ...
32
34 if [-n "\{10\}"] # Parameters > $9 must be enclosed in {brackets}.
36 echo "Parameter #10 is ${10}"
37 fi
38
39 echo "-----"
40 echo "All the command-line parameters are: "$*""
42 if [ $# -lt "$MINPARAMS" ]
43 then
   echo
    echo "This script needs at least $MINPARAMS command-line arguments!"
46 fi
47
48 echo
49
50 exit 0
```

Bracket notation for positional parameters leads to a fairly simple way of referencing the *last* argument passed to a script on the command line. This also requires <u>indirect referencing</u>.

Some scripts can perform different operations, depending on which name they are invoked with. For this to work, the script needs to check \$0, the name it was invoked by. There must also exist symbolic links to all the alternate names of the script. See Example 15-2.

i If a script expects a command line parameter but is invoked without one, this may cause a *null variable assignment*, generally an undesirable result. One way to prevent this is to append an extra character to both sides of the assignment statement using the expected positional parameter.

```
1 variable1_=$1_ # Rather than variable1=$1
```

```
2 # This will prevent an error, even if positional parameter is absent.
  4 critical_argument01=$variable1_
  6 # The extra character can be stripped off later, like so.
  7 variable1=${variable1_/_/}
  8 # Side effects only if $variable1_ begins with an underscore.
  9 # This uses one of the parameter substitution templates discussed later.
 10 # (Leaving out the replacement pattern results in a deletion.)
 11
 12 # A more straightforward way of dealing with this is
 13 #+ to simply test whether expected positional parameters have been passed.
 14 if [ -z $1 ]
 15 then
 16 exit $E_MISSING_POS_PARAM
 17 fi
 18
 19
 20 # However, as Fabian Kreutz points out,
 21 #+ the above method may have unexpected side-effects.
 22 # A better method is parameter substitution:
              ${1:-$DefaultVal}
 24 # See the "Parameter Substition" section
25 #+ in the "Variables Revisited" chapter.
```

Example 4-6. wh, whois domain name lookup

```
1 #!/bin/bash
 2 # ex18.sh
 4 # Does a 'whois domain-name' lookup on any of 3 alternate servers:
 5 #
                       ripe.net, cw.net, radb.net
 7 \# Place this script -- renamed 'wh' -- in /usr/local/bin
 9 # Requires symbolic links:
10 # ln -s /usr/local/bin/wh /usr/local/bin/wh-ripe
11 # ln -s /usr/local/bin/wh /usr/local/bin/wh-cw
12 # ln -s /usr/local/bin/wh /usr/local/bin/wh-radb
13
14 E_NOARGS=65
15
16
17 if [ -z "$1" ]
18 then
19 echo "Usage: `basename $0` [domain-name]"
20 exit $E_NOARGS
21 fi
22
23 # Check script name and call proper server.
24 case `basename $0` in $\# Or: case $\{0\#\#*/\}$ in
25
      "wh" ) whois $1@whois.ripe.net;;
26
       "wh-ripe") whois $1@whois.ripe.net;;
       "wh-radb") whois $1@whois.radb.net;;
       "wh-cw" ) whois $1@whois.cw.net;;
28
         ) echo "Usage: `basename $0` [domain-name]";;
29
30 esac
31
32 exit $?
```

The **shift** command reassigns the positional parameters, in effect shifting them to the left one notch.

```
$1 <--- $2, $2 <--- $3, $3 <--- $4, etc.
```

The old \$1 disappears, but \$0 (the script name) does not change. If you use a large number of positional parameters to a script, **shift** lets you access those past 10, although $\{bracket\}$ notation also permits this.

Example 4-7. Using shift

```
1 #!/bin/bash
 2 # shft.sh: Using 'shift' to step through all the positional parameters
 4 # Name this script something like shft.sh,
 5 #+ and invoke it with some parameters.
 6 #+ For example:
7 # sh shft.sh a b c def 23 skidoo
9 until [ -z "$1" ] # Until all parameters used up . . .
10 do
11 echo -n "$1 "
12 shift
13 done
1.4
          # Extra line feed.
15 echo
16
17 exit 0
19 # See also the echo-params.sh script for a "shiftless"
20 #+ alternative method of stepping through the positional params.
```

The **shift** command can take a numerical parameter indicating how many positions to shift.

```
1 #!/bin/bash
2 # shift-past.sh
 4 shift 3 # Shift 3 positions.
 5 \# n=3; shift n
 6 # Has the same effect.
8 echo "$1"
10 exit 0
11
12 # ======= #
13
14
15 $ sh shift-past.sh 1 2 3 4 5
16 4
17
18 # However, as Eleni Fragkiadaki, points out,
19 #+ attempting a 'shift' past the number of
20 #+ positional parameters ($#) returns an exit status of 0,
21 #+ and the positional parameters themselves do not change.
22 # This means possibly getting stuck in an endless loop. . .
23 # For example:
24 # until [ -z "$1" ]
25 #
26 # echo -n "$1 "
27 # shift 20 # If less than 20 pos params,
28 # done #+ then loop never ends!
```

```
29 #
30 # When in doubt, add a sanity check...
31 # shift 20 || break
32 # ^^^^^^
```

The **shift** command works in a similar fashion on parameters passed to a <u>function</u>. See <u>Example 33-15</u>.

Notes

[1] The process calling the script sets the \$0 parameter. By convention, this parameter is the name of the script. See the <u>manpage</u> for **execv**.

<u>Prev</u>	<u>Home</u>	<u>Next</u>	
Bash Variables Are Untyped	<u>Up</u>	Quoting	
Advanced Bash-Scripting Guide: An in-depth exploration of the art of shell scripting			
<u>Prev</u>		<u>Next</u>	

Chapter 5. Quoting

Quoting means just that, bracketing a string in quotes. This has the effect of protecting <u>special characters</u> in the string from reinterpretation or expansion by the shell or shell script. (A character is "special" if it has an interpretation other than its literal meaning, such as the wild card character -- *.)

In everyday speech or writing, when we "quote" a phrase, we set it apart and give it special meaning. In a Bash script, when we *quote* a string, we set it apart and protect its *literal* meaning.

Certain programs and utilities reinterpret or expand special characters in a quoted string. An important use of quoting is protecting a command-line parameter from the shell, but still letting the calling program expand it.

```
bash$ grep '[Ff]irst' *.txt
file1.txt:This is the first line of file1.txt.
file2.txt:This is the First line of file2.txt.
```

Note that the unquoted grep [Ff]irst *.txt works under the Bash shell. [1]

Quoting can also suppress echo's "appetite" for newlines.

```
bash$ echo $(ls -1)
total 8 -rw-rw-r-- 1 bo bo 13 Aug 21 12:57 t.sh -rw-rw-r-- 1 bo bo 78 Aug 21 12:57 u.sh

bash$ echo "$(ls -1)"
total 8
-rw-rw-r-- 1 bo bo 13 Aug 21 12:57 t.sh
-rw-rw-r-- 1 bo bo 78 Aug 21 12:57 u.sh
```

5.1. Quoting Variables

When referencing a variable, it is generally advisable to enclose its name in double quotes. This prevents reinterpretation of all special characters within the quoted string -- the variable name [2] -- except \$, ` (backquote), and \ (escape). [3] Keeping \$ as a special character within double quotes permits referencing a quoted variable ("\$variable"), that is, replacing the variable with its value (see Example 4-1, above).

Use double quotes to prevent word splitting. [4] An argument enclosed in double quotes presents itself as a single word, even if it contains whitespace separators.

```
1 variable1="a variable containing five words"
 2 COMMAND This is $variable1  # Executes COMMAND with 7 arguments:
 3 # "This" "is" "a" "variable" "containing" "five" "words"
 5 COMMAND "This is $variable1" # Executes COMMAND with 1 argument:
 6 # "This is a variable containing five words"
 8
 9 variable2="" # Empty.
10
11 COMMAND $variable2 $variable2 $variable2
12 # Executes COMMAND with no arguments.
13 COMMAND "$variable2" "$variable2" "$variable2"
# Executes COMMAND with 3 empty arguments.
15 COMMAND "$variable2 $variable2 $variable2"
16
                # Executes COMMAND with 1 argument (2 spaces).
17
18 # Thanks, Stéphane Chazelas.
```

i Enclosing the arguments to an **echo** statement in double quotes is necessary only when word splitting or preservation of <u>whitespace</u> is an issue.

Example 5-1. Echoing Weird Variables

```
1 #!/bin/bash
2 # weirdvars.sh: Echoing weird variables.
3
4 var="'(]\\{}\$\""
5 echo $var  # '(]\\{}\$" Doesn't make a difference.
7
8 echo
9
10 IFS='\'
11 echo $var  # '(] \{}\$" \ converted to space. Why?
12 echo "$var"  # '(]\\{}\$"
13
14 # Examples above supplied by Stephane Chazelas.
15
16 exit 0
```

Single quotes ('') operate similarly to double quotes, but do not permit referencing variables, since the special meaning of \$ is turned off. Within single quotes, *every* special character except 'gets interpreted literally. Consider single quotes ("full quoting") to be a stricter method of quoting than double quotes ("partial quoting").

Since even the escape character (\) gets a literal interpretation within single quotes, trying to enclose a single quote within single quotes will not yield the expected result.

Notes

- Unless there is a file named first in the current working directory. Yet another reason to *quote*. (Thank you, Harald Koenig, for pointing this out.
- [2] It also has side-effects on the *value* of the variable (see below)
- [3] Encapsulating "!" within double quotes gives an error when used *from the command line*. This is interpreted as a <u>history command</u>. Within a script, though, this problem does not occur, since the Bash history mechanism is disabled then.

Of more concern is the *apparently* inconsistent behavior of "\" within double quotes.

```
bash$ echo hello\!
bash$ echo "hello\!"
hello\!

bash$ echo -e x\ty
xty

bash$ echo -e "x\ty"
x y
```

What happens is that double quotes normally *escape* the "\" escape character, so that it echoes literally. However, the -e option to *echo* changes that. It causes the "\t" to be interpreted as a *tab*.

(Thank you, Wayne Pollock, for pointing this out, and Geoff Lee for explaining it.)

[4] "Word splitting", in this context, means dividing a character string into a number of separate and discrete arguments.

PrevHomeNextSpecial Variable TypesUpEscapingAdvanced Bash-Scripting Guide: An in-depth exploration of the art of shell scriptingPrevChapter 5. QuotingNext

5.2. Escaping

Escaping is a method of quoting single characters. The escape (\) preceding a character tells the shell to interpret that character literally.

1 With certain commands and utilities, such as echo and sed, escaping a character may have the opposite effect - it can toggle on a special meaning for that character.

Special meanings of certain escaped characters

```
used with echo and sed
        means newline
\r
        means return
\t
        means tab
\v
        means vertical tab
\b
        means backspace
\a
        means "alert" (beep or flash)
\langle 0xx \rangle
        translates to the octal ASCII equivalent of 0xx
```

Example 5-2. Escaped Characters

```
1 #!/bin/bash
2 # escaped.sh: escaped characters
4 echo; echo
6 # Escaping a newline.
8
9 echo ""
10
11 echo "This will print
12 as two lines."
13 # This will print
14 # as two lines.
15
16 echo "This will print \
17 as one line."
18 # This will print as one line.
19
20 echo; echo
21
22 echo "========"
2.3
24
25 echo "\v\v\v" # Prints \v\v\v\ literally.
26 # Use the -e option with 'echo' to print escaped characters.
27 echo "======="
28 echo "VERTICAL TABS"
29 echo -e "\v\v\v" # Prints 4 vertical tabs.
30 echo "======="
```

```
31
32 echo "QUOTATION MARK"
33 echo -e "\042" # Prints " (quote, octal ASCII character 42).
34 echo "========"
36 # The $'\X' construct makes the -e option unnecessary.
37 echo; echo "NEWLINE AND BEEP"
38 echo $'\n' # Newline.
                     # Alert (beep).
39 echo $'\a'
40
41 echo "========="
42 echo "QUOTATION MARKS"
43 # Version 2 and later of Bash permits using the $'\nnn' construct.
44 # Note that in this case, '\nnn' is an octal value.
45 echo \dagger \t 042 \t \ # Quote (") framed by tabs.
47 # It also works with hexadecimal values, in an $'\xhhh' construct.
48 echo \frac{1}{x}22 \t' # Quote (") framed by tabs.
49 # Thank you, Greg Keraunen, for pointing this out.
50 # Earlier Bash versions allowed '\times022'.
51 echo "========"
52 echo
53
54
5.5
56
57
58 # Assigning ASCII characters to a variable.
60 quote=$'\042' # " assigned to a variable.
61 echo "$quote This is a quoted string, $quote and this lies outside the quotes."
63 echo
64
65 # Concatenating ASCII chars in a variable.
67 echo "$triple_underline UNDERLINE $triple_underline"
69 echo
70
71 ABC=$'\101\102\103\010'
                                # 101, 102, 103 are octal A, B, C.
72 echo $ABC
73
74 echo; echo
75
76 escape=$'\033'
                              # 033 is octal for escape.
77 echo "\"escape\" echoes as $escape"
78 #
                                   no visible output.
79
80 echo; echo
81
82 exit 0
```

See Example 34-1 for another example of the \$' ' string expansion construct.

gives the quote its literal meaning

\"

\\$

```
1 echo "Hello" # Hello
2 echo "\"Hello\", he said." # "Hello", he said.
```

gives the dollar sign its literal meaning (variable name following \\$ will not be referenced)

```
1 echo "\$variable01"  # results in $variable01
```

gives the backslash its literal meaning

```
1 echo "\" # Results in \
2
3 # Whereas . . .
4
5 echo "\" # Invokes secondary prompt from the command line.
6 # In a script, gives an error message.
```

The behavior of \ depends on whether it is itself escaped, quoted, or appearing within <u>command</u> substitution or a <u>here document</u>.

```
# Simple escaping and quoting
 2 echo \z
                           # z
                           # \z
 3 echo \\z
 4 echo '\z'
                           # \z
                         # \\z
 5 echo '\\z'
 6 echo "\z"
7 echo "\\z"
                          #\z
                           # \z
# Command substitution

10 echo `echo \z`  # z

11 echo `echo \\z`  # z

12 echo `cch `
12 echo `echo \\\z`
13 echo `echo \\\z` # \z
14 echo `cc' # \z
14 echo `echo \\\\\z` # \z
15 echo `echo \\\\\z` # \\z
16 echo `echo "\z"`  # \z
17 echo `echo "\\z"`  # \z
18
19
                           # Here document
20 cat <<EOF
21 \z
22 EOF
                           # \z
23
24 cat <<EOF
25 \\z
26 EOF
                            #\z
28 # These examples supplied by Stéphane Chazelas.
```

Elements of a string assigned to a variable may be escaped, but the escape character alone may not be assigned to a variable.

```
1 variable=\
 2 echo "$variable"
 3 # Will not work - gives an error message:
 4 # test.sh: : command not found
 5 # A "naked" escape cannot safely be assigned to a variable.
 7 \# What actually happens here is that the "\" escapes the newline and
 8 #+ the effect is variable=echo "$variable"
9 #+
                        invalid variable assignment
10
11 variable=\
12 23skidoo
13 echo "$variable" # 23skidoo
                        # This works, since the second line
14
15
                         #+ is a valid variable assignment.
16
17 variable=\
18 # \^ escape followed by space
19 echo "$variable" # space
```

```
21 variable=\\
22 echo "$variable"
                      # \
24 variable=\\\
25 echo "$variable"
26 # Will not work - gives an error message:
27 # test.sh: \: command not found
28 #
29 # First escape escapes second one, but the third one is left "naked",
30 #+ with same result as first instance, above.
31
32 variable=\\\\
                           # \\
33 echo "$variable"
34
                           # Second and fourth escapes escaped.
35
                           # This is o.k.
```

Escaping a space can prevent word splitting in a command's argument list.

```
1 file_list="/bin/cat /bin/gzip /bin/more /usr/bin/less /usr/bin/emacs-20.7"
2 # List of files as argument(s) to a command.
3
4 # Add two files to the list, and list all.
5 ls -l /usr/X11R6/bin/xsetroot /sbin/dump $file_list
6
7 echo "-------"
8
9 # What happens if we escape a couple of spaces?
10 ls -l /usr/X11R6/bin/xsetroot\ /sbin/dump\ $file_list
11 # Error: the first three files concatenated into a single argument to 'ls -l'
12 # because the two escaped spaces prevent argument (word) splitting.
```

The escape also provides a means of writing a multi-line command. Normally, each separate line constitutes a different command, but an escape at the end of a line *escapes the newline character*, and the command sequence continues on to the next line.

```
1 (cd /source/directory && tar cf - . ) | \
2 (cd /dest/directory && tar xpvf -)
3 # Repeating Alan Cox's directory tree copy command,
4 # but split into two lines for increased legibility.
5
6 # As an alternative:
7 tar cf - -C /source/directory . |
8 tar xpvf - -C /dest/directory
9 # See note below.
10 # (Thanks, Stéphane Chazelas.)
```

If a script line ends with a l, a pipe character, then a \, an escape, is not strictly necessary. It is, however, good programming practice to always escape the end of a line of code that continues to the following line.

```
1 echo "foo
2 bar"
3 #foo
4 #bar
5
6 echo
7
8 echo 'foo
9 bar' # No difference yet.
10 #foo
11 #bar
12
13 echo
```

```
14
15 echo foo\
16 bar # Newline escaped.
17 #foobar
19 echo
20
21 echo "foo\
22 bar" # Same here, as \ still interpreted as escape within weak quotes.
23 #foobar
24
25 echo
26
27 echo 'foo\
28 bar' # Escape character \ taken literally because of strong quoting.
29 #foo\
30 #bar
32 # Examples suggested by Stéphane Chazelas.
```

Chapter 6. Exit and Exit Status

...there are dark corners in the Bourne shell, and people use all of them.

-- Chet Ramey

The **exit** command may be used to terminate a script, just as in a *C* program. It can also return a value, which is available to the script's parent process.

Every command returns an *exit status* (sometimes referred to as a *return status* or *exit code*). A successful command returns a 0, while an unsuccessful one returns a non-zero value that usually may be interpreted as an error code. Well-behaved UNIX commands, programs, and utilities return a 0 exit code upon successful completion, though there are some exceptions.

Likewise, functions within a script and the script itself return an exit status. The last command executed in the function or script determines the exit status. Within a script, an **exit** *nnn* command may be used to deliver an *nnn* exit status to the shell (*nnn* must be a decimal number in the 0 - 255 range).

When a script ends with an **exit** that has no parameter, the exit status of the script is the exit status of the last command executed in the script (previous to the **exit**).

```
1 #!/bin/bash
2
3 COMMAND_1
4
5 . . .
6
7 # Will exit with status of last command.
8 COMMAND_LAST
9
10 exit
```

The equivalent of a bare **exit** is **exit** \$? or even just omitting the **exit**.

```
1 #!/bin/bash
2
3 COMMAND_1
4
5 . . .
6
7 # Will exit with status of last command.
8 COMMAND_LAST
9
10 exit $?
```

```
1 #!/bin/bash
2
3 COMMAND1
4
5 . . .
6
7 # Will exit with status of last command.
8 COMMAND_LAST
```

\$? reads the exit status of the last command executed. After a function returns, \$? gives the exit status of the last command executed in the function. This is Bash's way of giving functions a "return value." After a script terminates, a \$? from the command line gives the exit status of the script, that is, the last command executed in the script, which is, by convention, **0** on success or an integer in the range 1 - 255 on error.

Example 6-1. exit / exit status

```
1 #!/bin/bash
 3 echo hello
 4 echo $?  # Exit status 0 returned because command executed successfully.
 6 lskdf
              # Unrecognized command.
 7 echo $?
              # Non-zero exit status returned because command failed to execute.
9 echo
10
11 exit 113
              # Will return 113 to shell.
12
              # To verify this, type "echo $?" after script terminates.
13
14 # By convention, an 'exit 0' indicates success,
15 #+ while a non-zero exit value means an error or anomalous condition.
```

<u>\$?</u> is especially useful for testing the result of a command in a script (see <u>Example 15-34</u> and <u>Example 15-19</u>).

The 1, the logical not qualifier, reverses the outcome of a test or command, and this affects its exit status.

Example 6-2. Negating a condition using!

```
# The "true" builtin.
 2 echo "exit status of \"true\" = $?"
                                           # 0
4 ! true
 5 echo "exit status of \"! true\" = $?"
                                           # 1
 6 # Note that the "!" needs a space between it and the command.
7 # !true leads to a "command not found" error
8 #
9 # The '!' operator prefixing a command invokes the Bash history mechanism.
10
11 true
12 !true
13 # No error this time, but no negation either.
14 # It just repeats the previous command (true).
15
16 # Thanks, Stéphane Chazelas and Kristopher Newsome.
```

1

Certain exit status codes have <u>reserved meanings</u> and should not be user-specified in a script.

 Tests

 Advanced Bash-Scripting Guide: An in-depth exploration of the art of shell scripting

 Prev
 Next

Chapter 7. Tests

Every reasonably complete programming language can test for a condition, then act according to the result of the test. Bash has the **test** command, various bracket and parenthesis operators, and the **if/then** construct.

7.1. Test Constructs

- An **if/then** construct tests whether the <u>exit status</u> of a list of commands is 0 (since 0 means "success" by UNIX convention), and if so, executes one or more commands.
- There exists a dedicated command called [(<u>left bracket</u> special character). It is a synonym for **test**, and a <u>builtin</u> for efficiency reasons. This command considers its arguments as comparison expressions or file tests and returns an exit status corresponding to the result of the comparison (0 for true, 1 for false).
- With version 2.02, Bash introduced the [[...]] *extended test command*, which performs comparisons in a manner more familiar to programmers from other languages. Note that [[is a <u>keyword</u>, not a command.

Bash sees [[\$a -lt \$b]] as a single element, which returns an exit status.

The ((...)) and let ... constructs also return an exit status of 0 if the arithmetic expressions they evaluate expand to a non-zero value. These <u>arithmetic expansion</u> constructs may therefore be used to perform arithmetic comparisons.

```
1 let "1<2" returns 0 (as "1<2" expands to "1")
2 (( 0 && 1 )) returns 1 (as "0 && 1" expands to "0")
```

An if can test any command, not just conditions enclosed within brackets.

```
1 if cmp a b &> /dev/null # Suppress output.
 2 then echo "Files a and b are identical."
 3 else echo "Files a and b differ."
4 fi
6 # The very useful "if-grep" construct:
8 if grep -q Bash file
9 then echo "File contains at least one occurrence of Bash."
10 fi
11
12 word=Linux
13 letter_sequence=inu
14 if echo "$word" | grep -q "$letter_sequence"
15 # The "-q" option to grep suppresses output.
16 then
17 echo "$letter_sequence found in $word"
19 echo "$letter_sequence not found in $word"
20 fi
21
22
23 if COMMAND WHOSE EXIT STATUS IS 0 UNLESS ERROR OCCURRED
24 then echo "Command succeeded."
25 else echo "Command failed."
26 fi
```

• An **if/then** construct can contain nested comparisons and tests.

```
1 if echo "Next *if* is part of the comparison for the first *if*."
2
3  if [[ $comparison = "integer" ]]
4    then (( a < b ))
5    else
6    [[ $a < $b ]]
7    fi</pre>
```

```
8
9 then
10 echo '$a is less than $b'
11 fi
```

This detailed "if-test" explanation courtesy of Stéphane Chazelas.

Example 7-1. What is truth?

```
1 #!/bin/bash
3 # Tip:
4 # If you're unsure of how a certain condition would evaluate,
5 #+ test it in an if-test.
7 echo
8
9 echo "Testing \"0\""
10 if [ 0 ] # zero
11 then
12 echo "0 is true."
13 else
14 echo "O is false."
15 fi
       # 0 is true.
16
17 echo
18
19 echo "Testing \"1\""
20 if [ 1 ] # one
21 then
22 echo "1 is true."
23 else
24 echo "1 is false."
25 fi
         # 1 is true.
26
27 echo
28
29 echo "Testing \"-1\""
30 if [-1] # minus one
31 then
32 echo "-1 is true."
33 else
34 echo "-1 is false."
35 fi
        \# -1 is true.
36
37 echo
38
39 echo "Testing \"NULL\""
40 if [] # NULL (empty condition)
41 then
42 echo "NULL is true."
43 else
44 echo "NULL is false."
45 fi # NULL is false.
46
47 echo
48
49 echo "Testing \"xyz\""
50 if [ xyz ] # string
51 then
52 echo "Random string is true."
53 else
54 echo "Random string is false."
55 fi # Random string is true.
56
```

```
57 echo
 58
 59 echo "Testing \"\$xyz\""
 60 if [ $xyz ] # Tests if $xyz is null, but...
                # it's only an uninitialized variable.
 62 then
 63 echo "Uninitialized variable is true."
 64 else
 65 echo "Uninitialized variable is false."
        # Uninitialized variable is false.
 66 fi
 67
 68 echo
 69
 70 echo "Testing \"-n \$xyz\""
 71 if [ -n "$xyz" ] # More pedantically correct.
 72 then
 73 echo "Uninitialized variable is true."
 74 else
 75 echo "Uninitialized variable is false."
 76 fi
         # Uninitialized variable is false.
 77
 78 echo
 79
 80
 81 xyz=
            # Initialized, but set to null value.
 83 echo "Testing \"-n \$xyz\""
 84 if [ -n "$xyz" ]
85 then
 86 echo "Null variable is true."
 87 else
 88 echo "Null variable is false."
 89 fi # Null variable is false.
 90
 91
 92 echo
 93
 94
 95 # When is "false" true?
 96
 97 echo "Testing \"false\""
 98 if [ "false" ] # It seems that "false" is just a string.
99 then
100 echo "\"false\" is true." #+ and it tests true.
101 else
102 echo "\"false\" is false."
103 fi # "false" is true.
104
105 echo
107 echo "Testing \"\$false\"" # Again, uninitialized variable.
108 if [ "$false" ]
109 then
110 echo "\"\$false\" is true."
111 else
112 echo "\"\$false\" is false."
                # "$false" is false.
113 fi
114
                 # Now, we get the expected result.
115
116 # What would happen if we tested the uninitialized variable "$true"?
117
118 echo
119
120 exit 0
```

Exercise. Explain the behavior of Example 7-1, above.

```
1 if [ condition-true ]
2 then
3   command 1
4   command 2
5   ...
6 else
7   # Optional (may be left out if not needed).
8   # Adds default code block executing if original condition tests false.
9   command 3
10   command 4
11   ...
12 fi
```

When *if* and *then* are on same line in a condition test, a semicolon must terminate the *if* statement. Both *if* and *then* are <u>keywords</u>. Keywords (or commands) begin statements, and before a new statement on the same line begins, the old one must terminate.

```
1 if [ -x "$filename" ]; then
```

Else if and elif

elif

elif is a contraction for else if. The effect is to nest an inner if/then construct within an outer one.

```
1 if [ condition1 ]
2 then
3    command1
4    command2
5    command3
6 elif [ condition2 ]
7  # Same as else if
8 then
9    command4
10    command5
11 else
12    default-command
13 fi
```

The if test condition—true construct is the exact equivalent of if [condition—true]. As it happens, the left bracket, [, is a token which invokes the **test** command. The closing right bracket,], in an if/test should not therefore be strictly necessary, however newer versions of Bash require it.

The **test** command is a Bash <u>builtin</u> which tests file types and compares strings. Therefore, in a Bash script, **test** does *not* call the external /usr/bin/test binary, which is part of the *sh-utils* package. Likewise, [does not call /usr/bin/[, which is linked to /usr/bin/test.

```
bash$ type test

test is a shell builtin
bash$ type '['
  [ is a shell builtin
bash$ type '[['
  [[ is a shell keyword
bash$ type ']]'
  ]] is a shell keyword
bash$ type ']'
bash: type: ]: not found
```

Example 7-2. Equivalence of test, /usr/bin/test, [], and /usr/bin/[

```
1 #!/bin/bash
 2.
3 echo
4
5 if test -z "$1"
7 echo "No command-line arguments."
8 else
9 echo "First command-line argument is $1."
10 fi
11
12 echo
13
14 if /usr/bin/test -z "$1"  # Equivalent to "test" builtin.
15 # ^^^^^^
                             # Specifying full pathname.
16 then
17 echo "No command-line arguments."
18 else
19 echo "First command-line argument is $1."
20 fi
21
22 echo
23
26 #+ Bash responds to a missing close-bracket with an error message.
28 echo "No command-line arguments."
29 else
30 echo "First command-line argument is $1."
31 fi
32
33 echo
34
35
36 if /usr/bin/[ -z "$1" ]
                            # Again, functionally identical to above.
37 # if /usr/bin/[ -z "$1"
                             # Works, but gives an error message.
38 #
                             # Note:
39 #
                               This has been fixed in Bash, version 3.x.
40 then
41
   echo "No command-line arguments."
42 else
43 echo "First command-line argument is $1."
44 fi
45
46 echo
47
48 exit 0
```

The [[]] construct is the more versatile Bash version of []. This is the *extended test command*, adopted from *ksh88*.

No filename expansion or word splitting takes place between [[and]], but there is parameter expansion and command substitution.

```
2
3 if [[ -e $file ]]
4 then
5 echo "Password file exists."
6 fi
```

- Using the [[...]] test construct, rather than [...] can prevent many logic errors in scripts. For example, the &&, ||, <, and > operators work within a [[]] test, despite giving an error within a [] construct.
- Following an **if**, neither the **test** command nor the test brackets ([] or [[]]) are strictly necessary.

```
1 dir=/home/bozo
2
3 if cd "$dir" 2>/dev/null; then # "2>/dev/null" hides error message.
4 echo "Now in $dir."
5 else
6 echo "Can't change to $dir."
7 fi
```

The "if COMMAND" construct returns the exit status of COMMAND.

Similarly, a condition within test brackets may stand alone without an **if**, when used in combination with a <u>list construct</u>.

```
1 var1=20
2 var2=22
3 [ "$var1" -ne "$var2" ] && echo "$var1 is not equal to $var2"
4
5 home=/home/bozo
6 [ -d "$home" ] || echo "$home directory does not exist."
```

The (()) construct expands and evaluates an arithmetic expression. If the expression evaluates as zero, it returns an exit status of 1, or "false". A non-zero expression returns an exit status of 0, or "true". This is in marked contrast to using the **test** and [] constructs previously discussed.

Example 7-3. Arithmetic Tests using (())

```
1 #!/bin/bash
2 # Arithmetic tests.
4 # The (( ... )) construct evaluates and tests numerical expressions.
5 # Exit status opposite from [ ... ] construct!
7 ((0))
8 echo "Exit status of \"(( 0 ))\" is $?."
                                                   # 1
10 ((1))
11 echo "Exit status of \"(( 1 ))\" is $?."
12
13 ((5 > 4))
                                                   # true
14 echo "Exit status of \"((5 > 4))\" is $?."
                                                   # 0
15
16 ((5 > 9))
                                                   # false
17 echo "Exit status of \"((5 > 9))\" is $?."
19 ((5 - 5))
20 echo "Exit status of \"((5-5))\" is $?."
21
22 ((5 / 4))
                                                   # Division o.k.
23 echo "Exit status of \"(( 5 / 4 ))\" is $?."
24
25 ((1/2))
                                                   # Division result < 1.
26 echo "Exit status of \"(( 1 / 2 ))\" is \$?."
                                                   # Rounded off to 0.
27
                                                   # 1
```

```
28
29 ((1 / 0)) 2>/dev/null # Illegal division by 0.
30 # ^^^^^^^^^^
31 echo "Exit status of \"((1 / 0))\" is $?." # 1
32
33 # What effect does the "2>/dev/null" have?
34 # What would happen if it were removed?
35 # Try removing it, then rerunning the script.
36
37 exit 0
```

7.2. File test operators

Returns true if...

```
-е
        file exists
-a
        file exists
        This is identical in effect to -e. It has been "deprecated," [1] and its use is discouraged.
-f
        file is a regular file (not a directory or device file)
-S
        file is not zero size
-d
        file is a directory
-b
        file is a block device (floppy, cdrom, etc.)
-c
        file is a character device (keyboard, modem, sound card, etc.)
-p
        file is a pipe
-h
        file is a symbolic link
-L
        file is a symbolic link
-S
        file is a socket
-t
        file (descriptor) is associated with a terminal device
        This test option may be used to check whether the stdin([ -t 0 ]) or stdout([ -t 1 ]) in
        a given script is a terminal.
-r
        file has read permission (for the user running the test)
-W
        file has write permission (for the user running the test)
-X
        file has execute permission (for the user running the test)
-g
        set-group-id (sgid) flag set on file or directory
        If a directory has the sqid flag set, then a file created within that directory belongs to the group that
        owns the directory, not necessarily to the group of the user who created the file. This may be useful
        for a directory shared by a workgroup.
-u
        set-user-id (suid) flag set on file
```

A binary owned by *root* with set-user-id flag set runs with *root* privileges, even when an ordinary user invokes it. [2] This is useful for executables (such as **pppd** and **cdrecord**) that need to access system hardware. Lacking the *suid* flag, these binaries could not be invoked by a *non-root* user.

```
-rwsr-xr-t 1 root 178236 Oct 2 2000 /usr/sbin/pppd
```

A file with the suid flag set shows an s in its permissions.

-k

```
sticky bit set
```

Commonly known as the *sticky bit*, the *save-text-mode* flag is a special type of file permission. If a file has this flag set, that file will be kept in cache memory, for quicker access. [3] If set on a directory, it restricts write permission. Setting the sticky bit adds a *t* to the permissions on the file or directory listing.

```
drwxrwxrwt 7 root 1024 May 19 21:26 tmp/
```

If a user does not own a directory that has the sticky bit set, but has write permission in that directory, she can only delete those files that she owns in it. This keeps users from inadvertently overwriting or deleting each other's files in a publicly accessible directory, such as /tmp. (The *owner* of the directory or *root* can, of course, delete or rename files there.)

```
you are owner of file

-G

group-id of file same as yours

-N

file modified since it was last read

f1 -nt f2

file f1 is newer than f2

f1 -ot f2

file f1 is older than f2

f1 -ef f2

files f1 and f2 are hard links to the same file

!

"not" -- reverses the sense of the tests above (returns true if condition absent).
```

Example 7-4. Testing for broken links

```
1 #!/bin/bash
 2 # broken-link.sh
3 # Written by Lee bigelow <ligelowbee@yahoo.com>
 4 # Used in ABS Guide with permission.
 6 # A pure shell script to find dead symlinks and output them quoted
 7 #+ so they can be fed to xargs and dealt with :)
 8 #+ eg. sh broken-link.sh /somedir /someotherdir|xargs rm
 9
10 # This, however, is a better method:
11 #
12 # find "somedir" -type 1 -print0|\
13 # xargs -r0 file|\
14 #
     grep "broken symbolic"|
     sed -e 's/^\|: *broken symbolic.*$/"/g'
15 #
16 #
17 #+ but that wouldn't be pure Bash, now would it.
18 # Caution: beware the /proc file system and any circular links!
19 #######################
20
21
22 # If no args are passed to the script set directories-to-search
23 #+ to current directory. Otherwise set the directories-to-search
```

```
24 #+ to the args passed.
27 [ $# -eq 0 ] && directorys=`pwd` || directorys=$@
2.8
29
30 # Setup the function linkchk to check the directory it is passed
31 #+ for files that are links and don't exist, then print them quoted.
32 # If one of the elements in the directory is a subdirectory then
33 #+ send that subdirectory to the linkcheck function.
34 ##########
35
36 linkchk () {
37
      for element in $1/*; do
         [ -h "$element" -a ! -e "$element" ] && echo \"$element\"
         [ -d "$element" ] && linkchk $element
       # Of course, '-h' tests for symbolic link, '-d' for directory.
41
42 }
43
44 # Send each arg that was passed to the script to the linkchk() function
45 #+ if it is a valid directoy. If not, then print the error message
46 #+ and usage info.
47 ##################
48 for directory in $directorys; do
      if [ -d $directory ]
   then linkchk $directory
         echo "$directory is not a directory"
53
          echo "Usage: $0 dir1 dir2 ..."
54
      fi
55 done
56
57 exit $?
```

<u>Example 28-1</u>, <u>Example 10-7</u>, <u>Example 10-3</u>, <u>Example 28-3</u>, and <u>Example A-1</u> also illustrate uses of the file test operators.

Notes

[1] Per the 1913 edition of Webster's Dictionary:

```
1 Deprecate
2 ...
3
4 To pray against, as an evil;
5 to seek to avert by prayer;
6 to desire the removal of;
7 to seek deliverance from;
8 to express deep regret for;
9 to disapprove of strongly.
```

- [2] Be aware that *suid* binaries may open security holes. The *suid* flag has no effect on shell scripts.
- [3] On modern UNIX systems, the sticky bit is no longer used for files, only on directories.

	Advanced Bash-Scripting Guide: An in-depth exploration of the a	rt of shell scripting
<u>Prev</u>	Chapter 7. Tests	Next

7.3. Other Comparison Operators

A binary comparison operator compares two variables or quantities. Note that integer and string comparison use a different set of operators.

integer comparison

```
-eq
       is equal to
       if [ "$a" -eq "$b" ]
-ne
       is not equal to
       if [ "$a" -ne "$b" ]
-gt
       is greater than
       if [ "$a" -gt "$b" ]
-ge
       is greater than or equal to
       if [ "$a" -ge "$b" ]
-lt
       is less than
       if [ "$a" -lt "$b" ]
-le
       is less than or equal to
       if [ "$a" -le "$b" ]
<
       is less than (within double parentheses)
       (("$a" < "$b"))
<=
       is less than or equal to (within double parentheses)
       (("$a" <= "$b"))
>
       is greater than (within double parentheses)
       (("$a" > "$b"))
>=
       is greater than or equal to (within double parentheses)
       (("$a" >= "$b"))
string comparison
=
       is equal to
```

if ["\$a" = "\$b"]

is equal to

if ["\$a" == "\$b"]

This is a synonym for =.

```
1 [[ $a == z* ]]  # True if $a starts with an "z" (pattern matching).
2 [[ $a == "z*" ]]  # True if $a is equal to z* (literal matching).
3
4 [ $a == z* ]  # File globbing and word splitting take place.
5 [ "$a" == "z*" ]  # True if $a is equal to z* (literal matching).
6
7 # Thanks, Stéphane Chazelas
```

is not equal to

!=

<

>

-n

 $-\mathbf{Z}$

This operator uses pattern matching within a [[...]] construct.

is less than, in ASCII alphabetical order

Note that the "<" needs to be escaped within a [] construct.

is greater than, in ASCII alphabetical order

```
if [[ "$a" > "$b" ]]
if [ "$a" \> "$b" ]
```

Note that the ">" needs to be escaped within a [] construct.

See Example 26-11 for an application of this comparison operator.

string is not "null."

1 The -n test absolutely requires that the string be quoted within the test brackets. Using an unquoted string with ! -z, or even just the unquoted string alone within test brackets (see Example 7-6) normally works, however, this is an unsafe practice. Always quote a tested string. [1]

string is "null, " that is, has zero length

Example 7-5. Arithmetic and string comparisons

```
1 #!/bin/bash
3 a = 4
4 b=5
6 # Here "a" and "b" can be treated either as integers or strings.
7 # There is some blurring between the arithmetic and string comparisons,
8 #+ since Bash variables are not strongly typed.
10 # Bash permits integer operations and comparisons on variables
11 #+ whose value consists of all-integer characters.
12 # Caution advised, however.
13
14 echo
15
16 if [ "$a" -ne "$b" ]
17 then
   echo "$a is not equal to $b"
18
19
   echo "(arithmetic comparison)"
20 fi
2.1
22 echo
23
24 if [ "$a" != "$b" ]
25 then
26 echo "$a is not equal to $b."
27 echo "(string comparison)"
28 # "4" != "5"
29 # ASCII 52 != ASCII 53
30 fi
31
32 # In this particular instance, both "-ne" and "!=" work.
33
34 echo
35
36 exit 0
```

Example 7-6. Testing whether a string is *null*

```
1 #!/bin/bash
 2 # str-test.sh: Testing null strings and unquoted strings,
 3 \#+ but not strings and sealing wax, not to mention cabbages and kings . . .
 5 # Using if [ ... ]
 8 # If a string has not been initialized, it has no defined value.
9 # This state is called "null" (not the same as zero).
1.0
11 if [ -n $string1 ]  # $string1 has not been declared or initialized.
12 then
13 echo "String \"string1\" is not null."
14 else
15 echo "String \"string1\" is null."
16 fi
17 # Wrong result.
18 # Shows $string1 as not null, although it was not initialized.
19
20
21 echo
2.2
23
```

```
24 # Lets try it again.
25
26 if [ -n "$string1" ] # This time, $string1 is quoted.
27 then
28 echo "String \"string1\" is not null."
30 echo "String \"string1\" is null."
31 fi
                       # Quote strings within test brackets!
32
33
34 echo
35
36
37 if [ $string1 ]  # This time, $string1 stands naked.
39 echo "String \"string1\" is not null."
40 else
41 echo "String \"string1\" is null."
42 fi
43 # This works fine.
44 # The [ ] test operator alone detects whether the string is null.
45 # However it is good practice to quote it ("$string1").
46 #
47 # As Stephane Chazelas points out,
48 # if [$string1] has one argument, "]"
49 # if [ "$string1" ] has two arguments, the empty "$string1" and "]"
50
51
52
53 echo
54
5.5
56
57 string1=initialized
58
59 if [ $string1 ]
                  # Again, $string1 stands naked.
60 then
   echo "String \"string1\" is not null."
62 else
63 echo "String \"string1\" is null."
64 fi
65 # Again, gives correct result.
66 # Still, it is better to quote it ("$string1"), because . . .
67
68
69 string1="a = b"
70
71 if [ $string1 ]  # Again, $string1 stands naked.
72 then
73 echo "String \"string1\" is not null."
74 else
75 echo "String \"string1\" is null."
76 fi
77 # Not quoting "$string1" now gives wrong result!
78
79 exit 0
80 # Thank you, also, Florian Wisser, for the "heads-up".
```

Example 7-7. zmore

```
1 #!/bin/bash
2 # zmore
```

```
4 #View gzipped files with 'more'
6 NOARGS=65
7 NOTFOUND=66
8 NOTGZIP=67
10 if [ $# -eq 0 ] # same effect as: if [ -z "$1" ]
11 # $1 can exist, but be empty: zmore "" arg2 arg3
13 echo "Usage: `basename $0` filename" >&2
   # Error message to stderr.
    exit $NOARGS
16 # Returns 65 as exit status of script (error code).
17 fi
19 filename=$1
21 if [ ! -f "$filename" ]  # Quoting $filename allows for possible spaces.
23 echo "File $filename not found!" >&2
24 # Error message to stderr.
25 exit $NOTFOUND
26 fi
27
28 if [ ${filename##*.} != "gz" ]
29 # Using bracket in variable substitution.
31 echo "File $1 is not a gzipped file!"
32 exit $NOTGZIP
33 fi
34
35 zcat $1 | more
36
37 # Uses the filter 'more.'
38 # May substitute 'less', if desired.
41 exit $?  # Script returns exit status of pipe.
42 # Actually "exit $?" is unnecessary, as the script will, in any case,
43 # return the exit status of the last command executed.
```

compound comparison

```
-a
logical and

exp1 -a exp2 returns true if both exp1 and exp2 are true.

ological or

exp1 -o exp2 returns true if either exp1 or exp2 are true.
```

These are similar to the Bash comparison operators && and II, used within double brackets.

```
1 [[ condition1 && condition2 ]]
The -o and -a operators work with the test command or occur within single test brackets.
1 if [ "$exp1" -a "$exp2" ]
```

Refer to Example 8-3, Example 26-17, and Example A-31 to see compound comparison operators in action.

Notes

As S.C. points out, in a compound test, even quoting the string variable might not suffice. [-n "\$string" -o "\$a" = "\$b"] may cause an error with some versions of Bash if \$string is empty. The safe way is to append an extra character to possibly empty variables, ["x\$string" != x -o "x\$a" = "x\$b"] (the "x's" cancel out).

Prev Chapter 7. Tests Next

7.4. Nested if/then Condition Tests

Condition tests using the **if/then** construct may be nested. The net result is equivalent to using the && compound comparison operator above.

```
1 if [ condition1 ]
2 then
3  if [ condition2 ]
4  then
5   do-something # But only if both "condition1" and "condition2" valid.
6  fi
7 fi
```

See Example 34-4 for an example of nested if/then condition tests.

7.5. Testing Your Knowledge of Tests

The systemwide xinitro file can be used to launch the X server. This file contains quite a number of *if/then* tests. The following is excerpted from an "ancient" version of xinitro (*Red Hat 7.1*, or thereabouts).

```
1 if [ -f $HOME/.Xclients ]; then
 2 exec $HOME/.Xclients
 3 elif [ -f /etc/X11/xinit/Xclients ]; then
   exec /etc/X11/xinit/Xclients
 5 else
 6
       # failsafe settings. Although we should never get here
        # (we provide fallbacks in Xclients as well) it can't hurt.
 8
       xclock -geometry 100x100-5+5 &
 9
       xterm -geometry 80x50-50+150 &
       if [ -f /usr/bin/netscape -a -f /usr/share/doc/HTML/index.html ]; then
1.0
11
               netscape /usr/share/doc/HTML/index.html &
12
       fi
13 fi
```

Explain the *test* constructs in the above snippet, then examine an updated version of the file, /etc/X11/xinit/xinitrc, and analyze the *if/then* test constructs there. You may need to refer ahead to the discussions of grep, sed, and regular expressions.

Chapter 8. Operations and Related Topics

8.1. Operators

assignment

variable assignment

Initializing or changing the value of a variable

=

All-purpose assignment operator, which works for both arithmetic and string assignments.

```
1 var=27
2 category=minerals # No spaces allowed after the "=".
```

 \bigcirc Do not confuse the "=" assignment operator with the <u>= test operator</u>.

```
= as a test operator
3 if [ "$string1" = "$string2" ]
4 then
     command
6 fi
8 # if [ "X$string1" = "X$string2" ] is safer,
9 #+ to prevent an error message should one of the variables be empty.
10 # (The prepended "X" characters cancel out.)
```

arithmetic operators

```
+
        plus
        minus
        multiplication
        division
**
        exponentiation
```

```
1 # Bash, version 2.02, introduced the "**" exponentiation operator.
3 let "z=5**3"
4 \text{ echo } "z = $z"
                 \# z = 125
```

%

modulo, or mod (returns the *remainder* of an integer division operation)

```
bash$ expr 5 % 3
```

5/3 = 1 with remainder 2

This operator finds use in, among other things, generating numbers within a specific range (see Example 9-26 and Example 9-30) and formatting program output (see Example 26-16 and Example A-6). It can even be used to generate prime numbers, (see Example A-16). Modulo turns up surprisingly often in various numerical recipes.

Example 8-1. Greatest common divisor

```
1 #!/bin/bash
 2 # gcd.sh: greatest common divisor
 3 # Uses Euclid's algorithm
 5 # The "greatest common divisor" (gcd) of two integers
 6 #+ is the largest integer that will divide both, leaving no remainder.
 8 # Euclid's algorithm uses successive division.
 9 # In each pass,
10 #+ dividend <--- divisor
11 #+ divisor <--- remainder
12 #+ until remainder = 0.
13 #+ The gcd = dividend, on the final pass.
15 # For an excellent discussion of Euclid's algorithm, see
16 #+ Jim Loy's site, http://www.jimloy.com/number/euclids.htm.
17
18
19 # -----
20 # Argument check
21 ARGS=2
22 E_BADARGS=65
23
24 if [ $# -ne "$ARGS" ]
25 then
26 echo "Usage: `basename $0` first-number second-number"
27 exit $E_BADARGS
28 fi
29 # ---
30
31
32 gcd ()
33 {
34
35 dividend=$1
                           # Arbitrary assignment.
36 divisor=$2
                            #! It doesn't matter which of the two is larger.
37
                            # Why not?
38
39
   remainder=1
                            # If uninitialized variable used in loop,
                            #+ it results in an error message
40
41
                            #+ on the first pass through loop.
42
43 until [ "$remainder" -eq 0 ]
44 do
let "remainder = $dividend % $divisor"
46
     dividend=$divisor  # Now repeat with 2 smallest numbers.
47
     divisor=$remainder
48 done
                           # Euclid's algorithm
49
50 }
                            # Last $dividend is the gcd.
51
52
53 gcd $1 $2
54
55 echo; echo "GCD of $1 and $2 = $dividend"; echo
56
57
58 # Exercise :
60 # Check command-line arguments to make sure they are integers,
61 #+ and exit the script with an appropriate error message if not.
62
63 exit 0
```

```
#=
    plus-equal (increment variable by a constant)

let "var += 5" results in var being incremented by 5.

#=
    minus-equal (decrement variable by a constant)

*=
    times-equal (multiply variable by a constant)

let "var *= 4" results in var being multiplied by 4.

/=
    slash-equal (divide variable by a constant)

%=
    mod-equal (remainder of dividing variable by a constant)
```

Arithmetic operators often occur in an expr or let expression.

Example 8-2. Using Arithmetic Operations

```
1 #!/bin/bash
2 # Counting to 11 in 10 different ways.
4 n=1; echo -n "$n "
6 let "n = n + 1" # let "n = n + 1" also works.
7 echo -n "$n "
8
10 : \$((n = \$n + 1))
11 # ":" necessary because otherwise Bash attempts
12 #+ to interpret "((n = n + 1))" as a command.
13 echo -n "$n "
14
15 ((n = n + 1))
16 # A simpler alternative to the method above.
17 # Thanks, David Lombard, for pointing this out.
18 echo -n "$n "
19
20 n=\$((\$n + 1))
21 echo -n "$n "
22
23 : [n = n + 1]
24 # ":" necessary because otherwise Bash attempts
25 #+ to interpret "$[n = $n + 1]" as a command.
26 # Works even if "n" was initialized as a string.
27 echo -n "$n "
28
29 n = [ n + 1 ]
30 # Works even if "n" was initialized as a string.
31 #* Avoid this type of construct, since it is obsolete and nonportable.
32 # Thanks, Stephane Chazelas.
33 echo -n "$n "
34
35 # Now for C-style increment operators.
36 # Thanks, Frank Wang, for pointing this out.
37
38 let "n++"
                      # let "++n" also works.
39 echo -n "$n "
40
```

```
41 (( n++ ))  # (( ++n ) also works.
42 echo -n "$n "
43
44 : $(( n++ ))  # : $(( ++n )) also works.
45 echo -n "$n "
46
47 : $[ n++ ]  # : $[ ++n ]] also works
48 echo -n "$n "
49
50 echo
51
52 exit 0
```

Integer variables in Bash are actually signed *long* (32-bit) integers, in the range of -2147483648 to 2147483647. An operation that takes a variable outside these limits will give an erroneous result.

```
1 a=2147483646
2 echo "a = $a"  # a = 2147483646
3 let "a+=1"  # Increment "a".
4 echo "a = $a"  # a = 2147483647
5 let "a+=1"  # increment "a" again, past the limit.
6 echo "a = $a"  # a = -2147483648
7  # ERROR (out of range)
```

As of version 2.05b, Bash supports 64-bit integers.

Bash does not understand floating point arithmetic. It treats numbers containing a decimal point as strings.

```
1 a=1.5
2
3 let "b = $a + 1.3" # Error.
4 # t2.sh: let: b = 1.5 + 1.3: syntax error in expression
5 # (error token is ".5 + 1.3")
6
7 echo "b = $b" # b=1
```

Use <u>bc</u> in scripts that that need floating point calculations or math library functions.

bitwise operators. The bitwise operators seldom make an appearance in shell scripts. Their chief use seems to be manipulating and testing values read from ports or <u>sockets</u>. "Bit flipping" is more relevant to compiled languages, such as C and C++, which provide direct access to system hardware.

bitwise operators

```
bitwise left shift (multiplies by 2 for each shift position)

left-shift-equal

let "var <<= 2" results in var left-shifted 2 bits (multiplied by 4)

bitwise right shift (divides by 2 for each shift position)

right-shift-equal (inverse of <<=)

bitwise AND

elite to the shift position of the shift pos
```

```
bitwise OR
=
       bitwise OR-equal
       bitwise NOT
Λ
       bitwise XOR
^=
       bitwise XOR-equal
logical (boolean) operators
!
       NOT
          1 if [ ! -f $FILENAME ]
          2 then
          3 ...
&&
       AND
          1 if [ $condition1 ] && [ $condition2 ]
          2 # Same as: if [ $condition1 -a $condition2 ]
          3 # Returns true if both condition1 and condition2 hold true...
          5 if [[ $condition1 && $condition2 ]]  # Also works.
          6 # Note that && operator not permitted within [ ... ] construct.
       & may also, depending on context, be used in an and list to concatenate commands.
\parallel
       OR
          1 if [ $condition1 ] || [ $condition2 ]
          2 # Same as: if [ $condition1 -o $condition2 ]
          3 # Returns true if either condition1 or condition2 holds true...
          5 if [[ $condition1 || $condition2 ]]  # Also works.
          6 # Note that || operator not permitted within [ ... ] construct.
```

Bash tests the exit status of each statement linked with a logical operator.

Example 8-3. Compound Condition Tests Using && and ||

```
1 #!/bin/bash
 2
 3 a = 24
 4 b=47
6 if [ "$a" -eq 24 ] && [ "$b" -eq 47 ]
7 then
8 echo "Test #1 succeeds."
9 else
10 echo "Test #1 fails."
11 fi
12
13 # ERROR: if [ "$a" -eq 24 && "$b" -eq 47 ]
14 #+ attempts to execute ' [ "$a" -eq 24 '
15 #+
             and fails to finding matching ']'.
16 #
```

```
17 # Note: if [[ $a -eq 24 && $b -eq 24 ]] works.
18 # The double-bracket if-test is more flexible
19 #+ than the single-bracket version.
20 # (The "&&" has a different meaning in line 17 than in line 6.)
21 # Thanks, Stephane Chazelas, for pointing this out.
23
24 if [ "$a" -eq 98 ] || [ "$b" -eq 47 ]
25 then
26 echo "Test #2 succeeds."
27 else
28 echo "Test #2 fails."
29 fi
30
31
32 # The -a and -o options provide
33 #+ an alternative compound condition test.
34 # Thanks to Patrick Callahan for pointing this out.
36
37 if [ "$a" -eq 24 -a "$b" -eq 47 ]
38 then
39 echo "Test #3 succeeds."
40 else
41 echo "Test #3 fails."
42 fi
43
45 if [ "$a" -eq 98 -o "$b" -eq 47 ]
46 then
47 echo "Test #4 succeeds."
48 else
49 echo "Test #4 fails."
50 fi
51
52
53 a=rhino
54 b=crocodile
55 if [ "$a" = rhino ] && [ "$b" = crocodile ]
56 then
57 echo "Test #5 succeeds."
58 else
59 echo "Test #5 fails."
60 fi
61
62 exit 0
```

The && and || operators also find use in an arithmetic context.

```
bash$ echo $(( 1 && 2 )) $((3 && 0)) $((4 || 0)) $((0 || 0)) 1 0 1 0
```

miscellaneous operators

Comma operator

The **comma operator** chains together two or more arithmetic operations. All the operations are evaluated (with possible *side effects* [1]), but only the last operation is returned.

```
1 let "t1 = ((5 + 3, 7 - 1, 15 - 4))"
2 echo "t1 = $t1" # t1 = 11
```

The comma operator finds use mainly in <u>for loops</u>. See <u>Example 10-12</u>.

Notes

[1] Side effects are, of course, unintended and usually undesirable consequences.

8.2. Numerical Constants

A shell script interprets a number as decimal (base 10), unless that number has a special prefix or notation. A number preceded by a 0 is octal (base 8). A number preceded by 0x is hexadecimal (base 16). A number with an embedded # evaluates as BASE#NUMBER (with range and notational restrictions).

Example 8-4. Representation of numerical constants

```
1 #!/bin/bash
 2 # numbers.sh: Representation of numbers in different bases.
4 # Decimal: the default
5 let "dec = 32"
 6 echo "decimal number = $dec"
                                          # 32
7 # Nothing out of the ordinary here.
10 # Octal: numbers preceded by '0' (zero)
11 let "oct = 032"
12 echo "octal number = $oct"
                                          # 26
13 # Expresses result in decimal.
14 # -----
1.5
17 # Hexadecimal: numbers preceded by '0x' or '0X'
18 let "hex = 0x32"
19 echo "hexadecimal number = $hex"
20
21 echo $((0x9abc))
                                           # 39612
22 # ^^ double-parentheses arithmetic expansion/evaluation
23 # Expresses result in decimal.
2.4
25
26
27 # Other bases: BASE#NUMBER
28 # BASE between 2 and 64.
29 # NUMBER must use symbols within the BASE range, see below.
30
31
32 let "bin = 2#111100111001101"
33 echo "binary number = $bin"
                                         # 31181
34
35 \text{ let "b32} = 32 # 77 "
36 echo "base-32 number = $b32"
                                         # 231
38 let "b64 = 64#@_"
39 echo "base-64 number = $b64"
                                          # 4031
40 # This notation only works for a limited range (2 - 64) of ASCII characters.
41 # 10 digits + 26 lowercase characters + 26 uppercase characters + @ + _
42
43
44 echo
4.5
46 echo $((36#zz)) $((2#10101010)) $((16#AF16)) $((53#1aA))
                                          # 1295 170 44822 3375
47
48
49
50 # Important note:
52 # Using a digit out of range of the specified base notation
53 #+ gives an error message.
```

```
55 let "bad_oct = 081"
56 # (Partial) error message output:
57 # bad_oct = 081: value too great for base (error token is "081")
58 # Octal numbers use only digits in the range 0 - 7.
59
60 exit 0 # Thanks, Rich Bartell and Stephane Chazelas, for clarification.
```

Chapter 9. Variables Revisited

Used properly, variables can add power and flexibility to scripts. This requires learning their subtleties and nuances.

9.1. Internal Variables

Builtin variables

variables affecting bash script behavior

\$BASH

the path to the Bash binary itself

```
bash$ echo $BASH /bin/bash
```

\$BASH ENV

an <u>environmental variable</u> pointing to a Bash startup file to be read when a script is invoked \$BASH_SUBSHELL

a variable indicating the <u>subshell</u> level. This is a new addition to Bash, <u>version 3</u>.

See Example 20-1 for usage.

\$BASH_VERSINFO[n]

a 6-element <u>array</u> containing version information about the installed release of Bash. This is similar to \$BASH_VERSION, below, but a bit more detailed.

```
1 # Bash version info:
3 for n in 0 1 2 3 4 5
    echo "BASH_VERSINFO[$n] = ${BASH_VERSINFO[$n]}"
 6 done
8 # BASH_VERSINFO[0] = 3
                                               # Major version no.
9 # BASH_VERSINFO[1] = 00
                                               # Minor version no.
10 \# BASH_VERSINFO[2] = 14
                                               # Patch level.
11 # BASH_VERSINFO[3] = 1
                                              # Build version.
12 # BASH_VERSINFO[4] = release
                                               # Release status.
13 # BASH_VERSINFO[5] = i386-redhat-linux-gnu # Architecture
14
                                               # (same as $MACHTYPE).
```

\$BASH_VERSION

the version of Bash installed on the system

```
bash$ echo $BASH_VERSION
3.00.14(1)-release
```

```
tcsh% echo $BASH_VERSION

BASH_VERSION: Undefined variable.
```

Checking \$BASH_VERSION is a good method of determining which shell is running. <u>\$SHELL</u> does not necessarily give the correct answer.

\$DIRSTACK

the top value in the directory stack (affected by <u>pushd</u> and <u>popd</u>)

This builtin variable corresponds to the <u>dirs</u> command, however **dirs** shows the entire contents of the directory stack.

SEDITOR

the default editor invoked by a script, usually vi or emacs.

\$EUID

"effective" user ID number

Identification number of whatever identity the current user has assumed, perhaps by means of <u>su</u>.

1 The \$EUID is not necessarily the same as the <u>\$UID</u>.

\$FUNCNAME

name of the current function

```
1 xyz23 ()
2 {
3
  echo "$FUNCNAME now executing." # xyz23 now executing.
4 }
6 xyz23
8 echo "FUNCNAME = $FUNCNAME"
                                    # FUNCNAME =
                                   # Null value outside a function.
```

\$GLOBIGNORE

A list of filename patterns to be excluded from matching in globbing. \$GROUPS

groups current user belongs to

This is a listing (array) of the group id numbers for current user, as recorded in /etc/passwd and /etc/group.

```
root# echo $GROUPS
 root# echo ${GROUPS[1]}
 1
 root# echo ${GROUPS[5]}
```

\$HOME

home directory of the user, usually /home/username (see Example 9-16)

The hostname command assigns the system host name at bootup in an init script. However, the gethostname () function sets the Bash internal variable \$HOSTNAME. See also Example 9-16. \$HOSTTYPE

host type

Like <u>\$MACHTYPE</u>, identifies the system hardware.

```
bash$ echo $HOSTTYPE
i686
```

\$IFS

internal field separator

This variable determines how Bash recognizes fields, or word boundaries, when it interprets character strings.

\$IFS defaults to whitespace (space, tab, and newline), but may be changed, for example, to parse a comma-separated data file. Note that <u>\$\\$*</u> uses the first character held in \$IFS. See <u>Example 5-1</u>.

```
bash$ echo "$IFS"
 (With $IFS set to default, a blank line displays.)
```

```
bash$ echo "$IFS" | cat -vte
^I$
(Show whitespace -- here space, ^I [horizontal tab],
and newline -- and display "$" at end-of-line.)
bash$ bash -c 'set w x y z; IFS=":-;"; echo "$*"'
(Read commands from string and assign any arguments to pos params.)
```

• \$IFS does not handle whitespace the same as it does other characters.

Example 9-1. \$IFS and whitespace

```
1 #!/bin/bash
2 # $IFS treats whitespace differently than other characters.
4 output_args_one_per_line()
5 {
6 for arg
   do echo "[$arg]"
7
8 done
9 }
10
11 echo; echo "IFS=\" \""
12 echo "----"
13
14 IFS=" "
15 var=" a b c
16 output_args_one_per_line $var # output_args_one_per_line `echo " a b c
17 #
18 # [a]
19 # [b]
20 # [c]
21
22
23 echo; echo "IFS=:"
24 echo "----"
25
26 IFS=:
27 var=":a::b:c:::"
                                # Same as above, but substitute ":" for " ".
28 output_args_one_per_line $var
29 #
30 # []
31 # [a]
32 # []
33 # [b]
34 # [c]
35 # []
36 # []
37 # []
38
39 # The same thing happens with the "FS" field separator in awk.
41 # Thank you, Stephane Chazelas.
42
43 echo
44
45 exit 0
```

(Many thanks, Stéphane Chazelas, for clarification and examples.)

See also Example 15-40, Example 10-7, and Example 18-14 for instructive examples of using \$IFS. \$IGNOREEOF

ignore EOF: how many end-of-files (control-D) the shell will ignore before logging out. LC COLLATE

Often set in the .bashrc or /etc/profile files, this variable controls collation order in filename expansion and pattern matching. If mishandled, LC_COLLATE can cause unexpected results in filename globbing.

As of version 2.05 of Bash, filename globbing no longer distinguishes between lowercase and uppercase letters in a character range between brackets. For example, **ls** [A-M]* would match both File1.txt and file1.txt. To revert to the customary behavior of bracket matching, set LC_COLLATE to C by an **export**

LC_COLLATE=C in /etc/profile and/or ~/.bashrc.

\$LC_CTYPE

This internal variable controls character interpretation in $\underline{\text{globbing}}$ and pattern matching. \$LINENO

This variable is the line number of the shell script in which this variable appears. It has significance only within the script in which it appears, and is chiefly useful for debugging purposes.

```
1 # *** BEGIN DEBUG BLOCK ***
2 last_cmd_arg=$_ # Save it.
3
4 echo "At line number $LINENO, variable \"v1\" = $v1"
5 echo "Last command argument processed = $last_cmd_arg"
6 # *** END DEBUG BLOCK ***
```

\$MACHTYPE

machine type

Identifies the system hardware.

```
bash$ echo $MACHTYPE i686
```

\$OLDPWD

old working directory ("OLD-print-working-directory", previous directory you were in) SOSTYPE

operating system type

```
bash$ echo $OSTYPE linux
```

\$PATH

path to binaries, usually /usr/bin/, /usr/X11R6/bin/, /usr/local/bin, etc.

When given a command, the shell automatically does a hash table search on the directories listed in the *path* for the executable. The path is stored in the <u>environmental variable</u>, \$PATH, a list of directories, separated by colons. Normally, the system stores the \$PATH definition in /etc/profile and/or ~/.bashrc (see <u>Appendix G</u>).

```
bash$ echo $PATH
/bin:/usr/bin:/usr/local/bin:/usr/X11R6/bin:/sbin:/usr/sbin
```

PATH=\${PATH}: /opt/bin appends the /opt/bin directory to the current path. In a script, it may be expedient to temporarily add a directory to the path in this way. When the script exits, this restores the original \$PATH (a child process, such as a script, may not change the environment of the

parent process, the shell).

The current "working directory", . /, is usually omitted from the \$PATH as a security

\$PIPESTATUS

Array variable holding exit status(es) of last executed foreground pipe. Interestingly enough, this does not necessarily give the same result as the exit status of the last executed command.

```
bash$ echo $PIPESTATUS
0
bash$ ls -al | bogus_command
bash: bogus_command: command not found
bash$ echo $PIPESTATUS
141
bash$ ls -al | bogus_command
bash: bogus_command: command not found
bash$ echo $?
127
```

The members of the \$PIPESTATUS array hold the exit status of each respective command executed in a pipe. \$PIPESTATUS[0] holds the exit status of the first command in the pipe, \$PIPESTATUS[1] the exit status of the second command, and so on.

1 The \$PIPESTATUS variable may contain an erroneous 0 value in a login shell (in releases prior to 3.0 of Bash).

```
tcsh% bash
bash$ who | grep nobody | sort
bash$ echo ${PIPESTATUS[*]}
```

The above lines contained in a script would produce the expected 0 1 0 output.

Thank you, Wayne Pollock for pointing this out and supplying the above example.

The \$PIPESTATUS variable gives unexpected results in some contexts.

```
bash$ echo $BASH_VERSION
3.00.14(1)-release
bash$ $ 1s | bogus_command | wc
bash: bogus_command: command not found
0 0
             0
bash$ echo ${PIPESTATUS[@]}
141 127 0
```

Chet Ramey attributes the above output to the behavior of ls. If ls writes to a pipe whose output is not read, then SIGPIPE kills it, and its exit status is 141. Otherwise its exit status is 0, as expected. This likewise is the case for tr.

\$PIPESTATUS is a "volatile" variable. It needs to be captured immediately after the pipe in question, before any other command intervenes.

```
bash$ $ 1s | bogus_command | wc
bash: bogus_command: command not found
```

```
0 0 0
bash$ echo ${PIPESTATUS[@]}
0 127 0
bash$ echo ${PIPESTATUS[@]}
0
```

The <u>pipefail option</u> may be useful in cases where \$PIPESTATUS does not give the desired information.

\$PPID

The \$PPID of a process is the process ID (pid) of its parent process. [1]

Compare this with the <u>pidof</u> command.

\$PROMPT_COMMAND

A variable holding a command to be executed just before the primary prompt, \$PS1 is to be displayed.

\$PS1

This is the main prompt, seen at the command line.

\$PS2

The secondary prompt, seen when additional input is expected. It displays as ">".

\$PS3

The tertiary prompt, displayed in a <u>select loop</u> (see <u>Example 10-29</u>).

\$PS4

The quartenary prompt, shown at the beginning of each line of output when invoking a script with the -x option. It displays as "+".

\$PWD

working directory (directory you are in at the time)

This is the analog to the <u>pwd</u> builtin command.

```
1 #!/bin/bash
3 E_WRONG_DIRECTORY=73
5 clear # Clear screen.
7 TargetDirectory=/home/bozo/projects/GreatAmericanNovel
8
9 cd $TargetDirectory
10 echo "Deleting stale files in $TargetDirectory."
12 if [ "$PWD" != "$TargetDirectory" ]
13 then
         # Keep from wiping out wrong directory by accident.
   echo "Wrong directory!"
    echo "In $PWD, rather than $TargetDirectory!"
    echo "Bailing out!"
     exit $E_WRONG_DIRECTORY
17
18 fi
19
20 rm -rf *
21 \text{ rm} .[A-Za-z0-9]*
                       # Delete dotfiles.
22 \# rm -f .[^.]* ... * to remove filenames beginning with multiple dots.
23 # (shopt -s dotglob; rm -f *) will also work.
24 # Thanks, S.C. for pointing this out.
26 # Filenames may contain all characters in the 0 - 255 range, except "/".
27 # Deleting files beginning with weird characters is left as an exercise.
```

```
29 # Various other operations here, as necessary.
30
31 echo
32 echo "Done."
33 echo "Old files deleted in $TargetDirectory."
34 echo
35
36
37 exit 0
```

\$REPLY

The default value when a variable is not supplied to <u>read</u>. Also applicable to <u>select</u> menus, but only supplies the item number of the variable chosen, not the value of the variable itself.

```
1 #!/bin/bash
 2 # reply.sh
 4 # REPLY is the default value for a 'read' command.
 6 echo
7 echo -n "What is your favorite vegetable? "
8 read
10 echo "Your favorite vegetable is $REPLY."
11 # REPLY holds the value of last "read" if and only if
12 #+ no variable supplied.
13
14 echo
15 echo -n "What is your favorite fruit? "
16 read fruit
17 echo "Your favorite fruit is $fruit."
18 echo "but..."
19 echo "Value of \$REPLY is still $REPLY."
20 # $REPLY is still set to its previous value because
21 #+ the variable $fruit absorbed the new "read" value.
22
23 echo
2.4
25 exit 0
```

\$SECONDS

The number of seconds the script has been running.

```
1 #!/bin/bash
3 TIME_LIMIT=10
4 INTERVAL=1
 6 echo
7 echo "Hit Control-C to exit before $TIME_LIMIT seconds."
8 echo
10 while [ "$SECONDS" -le "$TIME_LIMIT" ]
11 do
   if [ "$SECONDS" -eq 1 ]
12
13
    then
14
    units=second
15
   else
16
    units=seconds
17
    fi
18
19
   echo "This script has been running $SECONDS $units."
2.0
   # On a slow or overburdened machine, the script may skip a count
21 #+ every once in a while.
22
   sleep $INTERVAL
23 done
```

```
24
25 echo -e "\a" # Beep!
26
27 exit 0
```

\$SHELLOPTS

the list of enabled shell options, a readonly variable

```
bash$ echo $SHELLOPTS
braceexpand:hashall:histexpand:monitor:history:interactive-comments:emacs
```

\$SHLVL

Shell level, how deeply Bash is nested. [2] If, at the command line, \$SHLVL is 1, then in a script it will increment to 2.

\$TMOUT

If the *\$TMOUT* environmental variable is set to a non-zero value time, then the shell prompt will time out after \$time seconds. This will cause a logout.

As of version 2.05b of Bash, it is now possible to use \$TMOUT in a script in combination with read.

```
1 # Works in scripts for Bash, versions 2.05b and later.
2
3 TMOUT=3 # Prompt times out at three seconds.
4
5 echo "What is your favorite song?"
6 echo "Quickly now, you only have $TMOUT seconds to answer!"
7 read song
8
9 if [ -z "$song" ]
10 then
11 song="(no answer)"
12 # Default response.
13 fi
14
15 echo "Your favorite song is $song."
```

There are other, more complex, ways of implementing timed input in a script. One alternative is to set up a timing loop to signal the script when it times out. This also requires a signal handling routine to trap (see Example 29-5) the interrupt generated by the timing loop (whew!).

Example 9-2. Timed Input

```
1 #!/bin/bash
2 # timed-input.sh
3
4 # TMOUT=3 Also works, as of newer versions of Bash.
7 TIMELIMIT=3 # Three seconds in this instance. May be set to different value.
9 PrintAnswer()
10 {
    if [ "$answer" = TIMEOUT ]
11
   then
12
13
     echo $answer
14
   else # Don't want to mix up the two instances.
   echo "Your favorite veggie is $answer"
```

```
kill $! # Kills no longer needed TimerOn function running in background.
16
17
                # $! is PID of last job running in background.
18
   fi
19
20 }
21
22
23
24 TimerOn()
25 {
   sleep $TIMELIMIT && kill -s 14 $$ &
2.7
   # Waits 3 seconds, then sends sigalarm to script.
28 }
29
30 Int14Vector()
31 {
32
   answer="TIMEOUT"
   PrintAnswer
33
34 exit 14
35 }
36
37 trap Int14Vector 14 # Timer interrupt (14) subverted for our purposes.
39 echo "What is your favorite vegetable "
40 TimerOn
41 read answer
42 PrintAnswer
43
44
45 # Admittedly, this is a kludgy implementation of timed input,
46 #+ however the "-t" option to "read" simplifies this task.
47 # See "t-out.sh", below.
48
49 # If you need something really elegant...
50 #+ consider writing the application in C or C++,
51 #+ using appropriate library functions, such as 'alarm' and 'setitimer'.
53 exit 0
```

An alternative is using stty.

Example 9-3. Once more, timed input

```
1 #!/bin/bash
 2 # timeout.sh
 4 # Written by Stephane Chazelas,
 5 #+ and modified by the document author.
 6
 7 INTERVAL=5
                          # timeout interval
8
9 timedout_read() {
10 timeout=$1
11 varname=$2
12 old_tty_settings=`stty -g`
13 stty -icanon min 0 time ${timeout}0
14 eval read $varname # or just read $varname
15 stty "$old_tty_settings"
16 # See man page for "stty".
17 }
18
19 echo; echo -n "What's your name? Quick! "
```

```
20 timedout_read $INTERVAL your_name
21
22 # This may not work on every terminal type.
23 # The maximum timeout depends on the terminal.
24 #+ (it is often 25.5 seconds).
26 echo
27
28 if [ ! -z "$your_name" ] # If name input before timeout...
30 echo "Your name is $your_name."
31 else
32 echo "Timed out."
33 fi
34
35 echo
36
37 # The behavior of this script differs somewhat from "timed-input.sh".
38 # At each keystroke, the counter resets.
40 exit 0
```

Perhaps the simplest method is using the -t option to read.

Example 9-4. Timed read

```
1 #!/bin/bash
 2 # t-out.sh
3 # Inspired by a suggestion from "syngin seven" (thanks).
 6 TIMELIMIT=4
                       # 4 seconds
 8 read -t $TIMELIMIT variable <&1
10 # In this instance, "<&1" is needed for Bash 1.x and 2.x,
11 # but unnecessary for Bash 3.x.
12
13 echo
14
15 if [ -z "$variable" ] # Is null?
16 then
17 echo "Timed out, variable still unset."
18 else
19 echo "variable = $variable"
20 fi
21
22 exit 0
```

\$UID

user ID number

current user's user identification number, as recorded in /etc/passwd

This is the current user's real id, even if she has temporarily assumed another identity through \underline{su} . \$UID is a readonly variable, not subject to change from the command line or within a script, and is the counterpart to the \underline{id} builtin.

Example 9-5. Am I root?

```
1 #!/bin/bash
 2 # am-i-root.sh: Am I root or not?
 4 ROOT_UID=0 # Root has $UID 0.
 6 if [ "$UID" -eq "$ROOT_UID" ] # Will the real "root" please stand up?
 7 then
8 echo "You are root."
9 else
10 echo "You are just an ordinary user (but mom loves you just the same)."
11 fi
12
13 exit 0
14
15
16 # =========== #
17 # Code below will not execute, because the script already exited.
19 # An alternate method of getting to the root of matters:
2.0
21 ROOTUSER_NAME=root
22
23 username=`id -nu`
                               # Or... username=`whoami`
24 if [ "$username" = "$ROOTUSER_NAME" ]
26 echo "Rooty, toot, toot. You are root."
27 else
28 echo "You are just a regular fella."
29 fi
```

See also Example 2-3.

The variables \$ENV, \$LOGNAME, \$MAIL, \$TERM, \$USER, and \$USERNAME are not Bash <u>builtins</u>. These are, however, often set as <u>environmental variables</u> in one of the Bash <u>startup files</u>. \$SHELL, the name of the user's login shell, may be set from /etc/passwd or in an "init" script, and it is likewise not a Bash builtin.

```
tcsh% echo $LOGNAME
bozo
tcsh% echo $SHELL
/bin/tcsh
tcsh% echo $TERM
rxvt

bash$ echo $LOGNAME
bozo
bash$ echo $SHELL
/bin/tcsh
bash$ echo $TERM
rxvt
```

Positional Parameters

\$*

\$0, \$1, \$2, etc.
positional parameters, passed from command line to script, passed to a function, or <u>set</u> to a variable (see <u>Example 4-5</u> and <u>Example 14-16</u>)
\$#
number of command line arguments [3] or positional parameters (see <u>Example 33-2</u>)

All of the positional parameters, seen as a single word

Same as \$*, but each parameter is a quoted string, that is, the parameters are passed on intact, without interpretation or expansion. This means, among other things, that each parameter in the argument list is seen as a separate word.

Of course, "\$@" should be quoted.

Example 9-6. arglist: Listing arguments with \$* and \$@

```
1 #!/bin/bash
 2 # arglist.sh
 3 # Invoke this script with several arguments, such as "one two three".
 5 E_BADARGS=65
 7 if [ ! -n "$1" ]
 8 then
9 echo "Usage: `basename $0` argument1 argument2 etc."
10 exit $E_BADARGS
11 fi
12
13 echo
14
15 index=1 # Initialize count.
17 echo "Listing args with \"\$*\":"
18 for arg in "$*" # Doesn't work properly if "$*" isn't quoted.
19 do
20
   echo "Arg #$index = $arg"
21 let "index+=1"
22 done
                   # $* sees all arguments as single word.
23 echo "Entire arg list seen as single word."
25 echo
26
27 index=1
                   # Reset count.
                   # What happens if you forget to do this?
2.8
30 echo "Listing args with \"\$@\":"
31 for arg in "$@"
32 do
33 echo "Arg #$index = $arg"
34 let "index+=1"
35 done # $@ sees arguments as separate words.
36 echo "Arg list seen as separate words."
37
38 echo
39
                 # Reset count.
41
42 echo "Listing args with \$* (unquoted):"
43 for arg in $*
44 do
   echo "Arg #$index = $arg"
4.5
46 let "index+=1"
47 done # Unquoted $* sees arguments as separate words.
48 echo "Arg list seen as separate words."
49
50 exit 0
```

Following a **shift**, the \$@ holds the remaining command-line parameters, lacking the previous \$1, which was lost.

```
1 #!/bin/bash
 2 # Invoke with ./scriptname 1 2 3 4 5
 4 echo "$@" # 1 2 3 4 5
 5 shift
 6 echo "$@" # 2 3 4 5
 7 shift
8 echo "$@" # 3 4 5
10 # Each "shift" loses parameter $1.
11 # "$@" then contains the remaining parameters.
```

The \$@ special parameter finds use as a tool for filtering input into shell scripts. The cat "\$@" construction accepts input to a script either from stdin or from files given as parameters to the script. See Example 15-23 and Example 15-24.

1 The \$* and \$@ parameters sometimes display inconsistent and puzzling behavior, depending on the setting of \$IFS.

Example 9-7. Inconsistent \$* and \$@ behavior

```
1 #!/bin/bash
 3 # Erratic behavior of the "$*" and "$@" internal Bash variables,
 4 #+ depending on whether they are quoted or not.
 5 # Inconsistent handling of word splitting and linefeeds.
 8 set -- "First one" "second" "third:one" "" "Fifth: :one"
9 # Setting the script arguments, $1, $2, etc.
10
11 echo
12
13 echo 'IFS unchanged, using "$*"'
14 c=0
15 for i in "$*"
                             # quoted
16 do echo "$((c+=1)): [$i]" # This line remains the same in every instance.
                            # Echo args.
18 done
19 echo ---
21 echo 'IFS unchanged, using $*'
22 c=0
23 for i in $*
                             # unquoted
24 do echo "$((c+=1)): [$i]"
25 done
26 echo ---
27
28 echo 'IFS unchanged, using "$@"'
29 c=0
30 for i in "$@"
31 do echo "$((c+=1)): [$i]"
32 done
33 echo ---
35 echo 'IFS unchanged, using $@'
36 c=0
37 for i in $@
38 do echo "$((c+=1)): [$i]"
```

```
39 done
40 echo ---
41
42 IFS=:
43 echo 'IFS=":", using "$*"'
45 for i in "$*"
46 do echo "$((c+=1)): [$i]"
47 done
48 echo ---
49
50 echo 'IFS=":", using $*'
51 c=0
52 for i in $*
53 do echo "$((c+=1)): [$i]"
 54 done
55 echo ---
56
57 var=$*
58 echo 'IFS=":", using "$var" (var=$*)'
59 c=0
60 for i in "$var"
61 do echo "$((c+=1)): [$i]"
62 done
63 echo ---
64
65 echo 'IFS=":", using $var (var=$*)'
66 c=0
67 for i in $var
68 do echo "$((c+=1)): [$i]"
69 done
70 echo ---
71
72 var="$*"
73 echo 'IFS=":", using $var (var="$*")'
74 c=0
75 for i in $var
 76 do echo "\$((c+=1)): [\$i]"
77 done
78 echo ---
79
80 echo 'IFS=":", using "$var" (var="$*")'
81 c=0
82 for i in "$var"
83 do echo "$((c+=1)): [$i]"
84 done
85 echo ---
87 echo 'IFS=":", using "$@"'
88 c=0
89 for i in "$@"
90 do echo "$((c+=1)): [$i]"
91 done
92 echo ---
93
94 echo 'IFS=":", using $@'
95 c=0
96 for i in $@
97 do echo "$((c+=1)): [$i]"
98 done
99 echo ---
100
101 var=$@
102 echo 'IFS=":", using $var (var=$@)'
103 c=0
104 for i in $var
```

```
105 do echo "$((c+=1)): [$i]"
106 done
107 echo ---
108
109 echo 'IFS=":", using "$var" (var=$@)'
111 for i in "$var"
112 do echo "$((c+=1)): [$i]"
113 done
114 echo ---
115
116 var="$@"
117 echo 'IFS=":", using "$var" (var="$@")'
118 c=0
119 for i in "$var"
120 do echo "$((c+=1)): [$i]"
121 done
122 echo ---
123
124 echo 'IFS=":", using $var (var="$@")'
125 c=0
126 for i in $var
127 do echo "$((c+=1)): [$i]"
128 done
129
130 echo
131
132 # Try this script with ksh or zsh -y.
134 exit 0
135
136 # This example script by Stephane Chazelas,
137 # and slightly modified by the document author.
```

The \$@ and \$* parameters differ only when between double quotes.

Example 9-8. \$* and \$@ when \$IFS is empty

```
1 #!/bin/bash
3 # If $IFS set, but empty,
4 #+ then "$*" and "$@" do not echo positional params as expected.
6 mecho ()
                # Echo positional parameters.
7 {
8 echo "$1,$2,$3";
9 }
10
11
12 IFS=""
                # Set, but empty.
13 set a b c
                 # Positional parameters.
15 mecho "$*"
                  # abc,,
16 mecho $*
                 # a,b,c
17
18 mecho $@
                 # a,b,c
19 mecho "$@"
                  # a,b,c
20
21 \# The behavior of * and * when *IFS is empty depends
22 #+ on whatever Bash or sh version being run.
23 # It is therefore inadvisable to depend on this "feature" in a script.
24
```

```
25
26 # Thanks, Stephane Chazelas.
27
28 exit 0
```

Other Special Parameters

\$-

Flags passed to script (using <u>set</u>). See <u>Example 14-16</u>.

1 This was originally a ksh construct adopted into Bash, and unfortunately it does not seem to work reliably in Bash scripts. One possible use for it is to have a script self-test whether it is interactive.

\$!

PID (process ID) of last job run in background

```
1 LOG=$0.log
3 COMMAND1="sleep 100"
 5 echo "Logging PIDs background commands for script: $0" >> "$LOG"
 6 # So they can be monitored, and killed as necessary.
 7 echo >> "$LOG"
9 # Logging commands.
10
11 echo -n "PID of \"$COMMAND1\": " >> "$LOG"
12 ${COMMAND1} &
13 echo $! >> "$LOG"
14 # PID of "sleep 100": 1506
16 # Thank you, Jacques Lederer, for suggesting this.
```

Using \$! for job control:

```
1 possibly_hanging_job & { sleep ${TIMEOUT}; eval 'kill -9 $!' &> /dev/null; }
2 # Forces completion of an ill-behaved program.
3 # Useful, for example, in init scripts.
5 # Thank you, Sylvain Fourmanoit, for this creative use of the "!" variable.
```

Or, alternately:

```
1 # This example by Matthew Sage.
 2 # Used with permission.
 4 TIMEOUT=30 # Timeout value in seconds
 5 count=0
 7 possibly_hanging_job & {
           while ((count < TIMEOUT )); do
                   eval '[ ! -d "/proc/$!" ] && ((count = TIMEOUT))'
 9
10
                   # /proc is where information about running processes is found.
11
                   # "-d" tests whether it exists (whether directory exists).
12
                   # So, we're waiting for the job in question to show up.
13
                   ((count++))
14
                   sleep 1
15
          done
16
          eval '[ -d "/proc/$!" ] && kill -15 $!'
17
           # If the hanging job is running, kill it.
18 }
```

Example 9-9. Underscore variable

\$?

Exit status of a command, function, or the script itself (see Example 23-7)

\$\$

Process ID of the script itself. The \$\$ variable often finds use in scripts to construct "unique" temp file names (see Example 29-6, Example 15-30, and Example 14-27). This is usually simpler than invoking mktemp.

Notes

- [1] The PID of the currently running script is \$\$, of course.
- [2] Somewhat analogous to <u>recursion</u>, in this context *nesting* refers to a pattern embedded within a larger pattern. One of the definitions of *nest*, according to the 1913 edition of *Webster's Dictionary*, illustrates this beautifully: "A collection of boxes, cases, or the like, of graduated size, each put within the one next larger."
- [3] The words "argument" and "parameter" are often used interchangeably. In the context of this document, they have the same precise meaning: *a variable passed to a script or function*.

 Manipulating Strings

 Advanced Bash-Scripting Guide: An in-depth exploration of the art of shell scripting

 Prev
 Chapter 9. Variables Revisited
 Next

9.2. Manipulating Strings

Bash supports a surprising number of string manipulation operations. Unfortunately, these tools lack a unified focus. Some are a subset of <u>parameter substitution</u>, and others fall under the functionality of the UNIX <u>expr</u> command. This results in inconsistent command syntax and overlap of functionality, not to mention confusion.

String Length

```
${#string}
expr length $string
expr "$string" : '.*'
```

```
1 stringZ=abcABC123ABCabc
2
3 echo ${#stringZ} # 15
4 echo `expr length $stringZ` # 15
5 echo `expr "$stringZ" : '.*'` # 15
```

Example 9-10. Inserting a blank line between paragraphs in a text file

```
1 #!/bin/bash
 2 # paragraph-space.sh
 4 # Inserts a blank line between paragraphs of a single-spaced text file.
 5 # Usage: $0 <FILENAME
 7 MINLEN=45 # May need to change this value.
 8 # Assume lines shorter than $MINLEN characters
 9 #+ terminate a paragraph.
 10
 11 while read line # For as many lines as the input file has...
13 echo "$line" # Output the line itself.
14
15
    len=${#line}
16 if [ "$len" -lt "$MINLEN" ]
     then echo # Add a blank line after short line.
17
18 fi
19 done
20
21 exit 0
```

Length of Matching Substring at Beginning of String

```
expr match "$string" '$substring'

$substring is a regular expression.

expr "$string": '$substring'

$substring is a regular expression.
```

```
1 stringZ=abcABC123ABCabc
2 #  |-----|
3
4 echo `expr match "$stringZ" 'abc[A-Z]*.2'` # 8
```

Index

expr index \$string \$substring

Numerical position in \$string of first character in \$substring that matches.

```
1 stringZ=abcABC123ABCabc
2 echo `expr index "$stringZ" C12` # 6
3 # C position.
4
5 echo `expr index "$stringZ" 1c` # 3
6 # 'c' (in #3 position) matches before '1'.
```

This is the near equivalent of *strchr()* in *C*.

Substring Extraction

\${string:position}

Extracts substring from \$string at \$position.

If the \$string parameter is "*" or "@", then this extracts the <u>positional parameters</u>, [1] starting at \$position.

\${string:position:length}

Extracts \$length characters of substring from \$string at \$position.

```
1 stringZ=abcABC123ABCabc
 2 # 0123456789....
         0-based indexing.
 3 #
 5 echo ${stringZ:0}
                                                # abcABC123ABCabc
 6 echo ${stringZ:1}
                                                # bcABC123ABCabc
 7 echo ${stringZ:7}
                                                # 23ABCabc
 9 echo ${stringZ:7:3}
                                                # 23A
10
                                                # Three characters of substring.
11
12
13
14 # Is it possible to index from the right end of the string?
15
16 echo ${stringZ:-4}
                                                # abcABC123ABCabc
17 # Defaults to full string, as in ${parameter:-default}.
18 # However . . .
19
20 echo ${stringZ: (-4)}
                                                # Cabc
21 echo ${stringZ: -4}
                                                # Cabc
22 # Now, it works.
23 # Parentheses or added space "escape" the position parameter.
25 # Thank you, Dan Jacobson, for pointing this out.
```

The *position* and *length* arguments can be "parameterized," that is, represented as a variable, rather than as a numerical constant.

Example 9-11. Generating an 8-character "random" string

```
1 #!/bin/bash
2 # rand-string.sh
3 # Generating an 8-character "random" string.
```

```
5 if [ "-n $1" ] # If command line argument present,
 6 then
                #+ then set start-string to it.
 7 str0="$1"
 8 else
                 # Else use PID of script as start-string.
 9 str0="$$"
10 fi
11
12 POS=2 # Starting from position 2 in the string.
13 LEN=8 # Extract eight characters.
15 str1=$( echo "$str0" | md5sum | md5sum )
16 # Doubly scramble: ^^^^^
17
18 randstring="${str1:$POS:$LEN}"
19 # Can parameterize ^^^^ ^^^
2.0
21 echo "$randstring"
22
23 exit $?
2.4
25 # bozo$ ./rand-string.sh my-password
26 # 1bdd88c4
27
28 # No, this is is not recommended
29 #+ as a method of generating hack-proof passwords.
```

If the \$string parameter is "*" or "@", then this extracts a maximum of \$length positional parameters, starting at \$position.

```
1 echo ${*:2}  # Echoes second and following positional parameters.
2 echo ${@:2}  # Same as above.
3
4 echo ${*:2:3}  # Echoes three positional parameters, starting at second.
```

expr substr \$string \$position \$length

Extracts \$length characters from \$string starting at \$position.

```
1 stringZ=abcABC123ABCabc
2 # 123456789.....
3 # 1-based indexing.
4
5 echo `expr substr $stringZ 1 2` # ab
6 echo `expr substr $stringZ 4 3` # ABC
```

expr match "\$string" \(\$substring\)'

Extracts \$ substring at beginning of \$ string, where \$ substring is a regular expression. expr "\$ string": '\(\\$ substring\)'

Extracts \$substring at beginning of \$string, where \$substring is a regular expression.

```
1 stringZ=abcABC123ABCabc
2 # ======
3
4 echo `expr match "$stringZ" '\(.[b-c]*[A-Z]..[0-9]\)'` # abcABC1
5 echo `expr "$stringZ" : '\(.[b-c]*[A-Z]..[0-9]\)'` # abcABC1
6 echo `expr "$stringZ" : '\(.....\)'` # abcABC1
7 # All of the above forms give an identical result.
```

expr match "\$string" '.*\(\$substring\)'

Extracts \$substring at end of \$string, where \$substring is a regular expression. expr "\$string": '.*\(\$substring\)'

Extracts \$substring at end of \$string, where \$substring is a regular expression.

```
1 stringZ=abcABC123ABCabc
```

```
2 # ======

3

4 echo `expr match "$stringZ" '.*\([A-C][A-C][A-C][a-c]*\)'` # ABCabc

5 echo `expr "$stringZ" : '.*\(.....\)'` # ABCabc
```

Substring Removal

\${string#substring}

Strips shortest match of \$substring from front of \$string.

\${string##substring}

Strips longest match of \$substring from front of \$string.

\${string%substring}

Strips shortest match of \$substring from back of \$string.

For example:

```
1 # Rename all filenames in $PWD with "TXT" suffix to a "txt" suffix.
2 # For example, "file1.TXT" becomes "file1.txt" . . .
3
4 SUFF=TXT
5 suff=txt
6
7 for i in $(ls *.$SUFF)
8 do
9  mv -f $i ${i%.$SUFF}.$suff
10 # Leave unchanged everything *except* the shortest pattern match
11 #+ starting from the right-hand-side of the variable $i . . .
12 done ### This could be condensed into a "one-liner" if desired.
13
14 # Thank you, Rory Winston.
```

\${string%%substring}

Strips longest match of \$substring from back of \$string.

This operator is useful for generating filenames.

Example 9-12. Converting graphic file formats, with filename change

```
1 #!/bin/bash
2 # cvt.sh:
3 # Converts all the MacPaint image files in a directory to "pbm" format.
```

```
5 # Uses the "macptopbm" binary from the "netpbm" package,
 6 #+ which is maintained by Brian Henderson (bryanh@giraffe-data.com).
7 # Netpbm is a standard part of most Linux distros.
9 OPERATION=macptopbm
10 SUFFIX=pbm
                    # New filename suffix.
11
12 if [ -n "$1" ]
13 then
14 directory=$1  # If directory name given as a script argument...
15 else
16 directory=$PWD # Otherwise use current working directory.
17 fi
18
19 # Assumes all files in the target directory are MacPaint image files,
20 #+ with a ".mac" filename suffix.
22 for file in $directory/* # Filename globbing.
2.3 do
24 filename=${file%.*c} # Strip ".mac" suffix off filename
2.5
                             #+ ('.*c' matches everything
                        #+ between '.' and 'c', inclusive).
2.6
28
                            # Redirect conversion to new filename.
29 rm -f $file
                            # Delete original files after converting.
30 echo "$filename.$SUFFIX" # Log what is happening to stdout.
31 done
32
33 exit 0
34
35 # Exercise:
36 # -----
37 \# As it stands, this script converts *all* the files in the current
38 #+ working directory.
39 \# Modify it to work *only* on files with a ".mac" suffix.
```

Example 9-13. Converting streaming audio files to ogg

```
1 #!/bin/bash
 2 # ra2ogg.sh: Convert streaming audio files (*.ra) to ogg.
 4 # Uses the "mplayer" media player program:
 5 # http://www.mplayerhq.hu/homepage
        Appropriate codecs may need to be installed for this script to work.
 7 # Uses the "ogg" library and "oggenc":
 8 #
        http://www.xiph.org/
10
11 OFILEPREF=${1%%ra} # Strip off the "ra" suffix.
12 OFILESUFF=wav
                         # Suffix for wav file.
13 OUTFILE="$OFILEPREF""$OFILESUFF"
14 E_NOARGS=65
15
16 if [ -z "$1" ]
                          # Must specify a filename to convert.
18 echo "Usage: `basename $0` [filename]"
19 exit $E_NOARGS
20 fi
21
22
```

```
24 mplayer "$1" -ao pcm:file=$OUTFILE
25 oggenc "$OUTFILE" # Correct file extension automatically added by oggenc.
27
28 rm "$OUTFILE"
                    # Delete intermediate *.wav file.
                      # If you want to keep it, comment out above line.
30
31 exit $?
32
33 # Note:
34 #
35 \# On a Website, simply clicking on a *.ram streaming audio file
36 #+ usually only downloads the URL of the actual audio file, the *.ra file.
37 # You can then use "wget" or something similar
38 #+ to download the *.ra file itself.
39
40
41 # Exercises:
42 #
43 # As is, this script converts only *.ra filenames.
44 # Add flexibility by permitting use of *.ram and other filenames.
45 #
46 # If you're really ambitious, expand the script
47 #+ to do automatic downloads and conversions of streaming audio files.
48 # Given a URL, batch download streaming audio files (using "wget")
49 #+ and convert them.
```

A simple emulation of getopt using substring extraction constructs.

Example 9-14. Emulating getopt

```
1 #!/bin/bash
2 # getopt-simple.sh
3 # Author: Chris Morgan
4 # Used in the ABS Guide with permission.
7 getopt_simple()
8 {
9
      echo "getopt_simple()"
1.0
     echo "Parameters are '$*'"
11
     until [ -z "$1" ]
12
      echo "Processing parameter of: '$1'"
1.3
       if [ ${1:0:1} = '/' ]
14
15
        then
           tmp=${1:1}
                                     # Strip off leading '/' . . .
           parameter=${tmp%%=*}
17
                                     # Extract name.
18
            value=${tmp##*=}
                                     # Extract value.
19
            echo "Parameter: '$parameter', value: '$value'"
2.0
            eval $parameter=$value
        fi
2.1
       shift
2.2
23
      done
24 }
25
26 # Pass all options to getopt_simple().
27 getopt_simple $*
29 echo "test is '$test'"
30 echo "test2 is '$test2'"
31
```

```
32 exit 0
33
34 ---
35
36 sh getopt_example.sh /test=value1 /test2=value2
37
38 Parameters are '/test=value1 /test2=value2'
39 Processing parameter of: '/test=value1'
40 Parameter: 'test', value: 'value1'
41 Processing parameter of: '/test2=value2'
42 Parameter: 'test2', value: 'value2'
43 test is 'value1'
44 test2 is 'value2'
```

Substring Replacement

\${string/substring/replacement}

Replace first match of \$substring with \$replacement.

\${string//substring/replacement}

Replace all matches of \$substring with \$replacement.

```
1 stringZ=abcABC123ABCabc
2
3 echo ${stringZ/abc/xyz}  # xyzABC123ABCabc
4  # Replaces first match of 'abc' with 'xyz'.
5
6 echo ${stringZ//abc/xyz}  # xyzABC123ABCxyz
7  # Replaces all matches of 'abc' with # 'xyz'.
```

\${string/#substring/replacement}

If \$substring matches front end of \$string, substitute \$replacement for \$substring. \${string/%substring/replacement}

If \$substring matches back end of \$string, substitute \$replacement for \$substring.

```
1 stringZ=abcABC123ABCabc
2
3 echo ${stringZ/#abc/XYZ}  # XYZABC123ABCabc
4  # Replaces front-end match of 'abc' with 'XYZ'.
5
6 echo ${stringZ/%abc/XYZ}  # abcABC123ABCXYZ
7  # Replaces back-end match of 'abc' with 'XYZ'.
```

9.2.1. Manipulating strings using awk

A Bash script may invoke the string manipulation facilities of <u>awk</u> as an alternative to using its built-in operations.

Example 9-15. Alternate ways of extracting substrings

```
1 #!/bin/bash
2 # substring-extraction.sh
3
4 String=23skidoo1
5 # 012345678 Bash
6 # 123456789 awk
7 # Note different string indexing system:
8 # Bash numbers first character of string as '0'.
```

9.2.2. Further Discussion

For more on string manipulation in scripts, refer to <u>Section 9.3</u> and the <u>relevant section</u> of the <u>expr</u> command listing. For script examples, see:

- 1. Example 15-9
- 2. Example 9-18
- 3. Example 9-19
- 4. Example 9-20
- 5. Example 9-22
- 6. Example A-38

Notes

[1] This applies to either command-line arguments or parameters passed to a <u>function</u>.

PrevHomeNextVariables RevisitedUpParameter SubstitutionAdvanced Bash-Scripting Guide: An in-depth exploration of the art of shell scriptingPrevChapter 9. Variables RevisitedNext

9.3. Parameter Substitution

Manipulating and/or expanding variables

\${parameter}

Same as \$parameter, i.e., value of the variable parameter. In certain contexts, only the less ambiguous \${parameter}\$ form works.

May be used for concatenating variables with strings.

```
1 your_id=${USER}-on-${HOSTNAME}
2 echo "$your_id"
3 #
4 echo "Old \$PATH = $PATH"
5 PATH=${PATH}:/opt/bin #Add /opt/bin to $PATH for duration of script.
6 echo "New \$PATH = $PATH"
```

\${parameter-default}, \${parameter:-default}

If parameter not set, use default.

```
1 echo ${username-`whoami`}
2 # Echoes the result of `whoami`, if variable $username is still unset.
```

\$\{\text{parameter-default}\}\ \text{and \$\{\text{parameter:-default}\}\ \text{are almost equivalent. The extra: makes a difference only when \$\text{parameter}\ \text{has been declared, but is null.}

```
1 #!/bin/bash
 2 # param-sub.sh
4 # Whether a variable has been declared
 5 #+ affects triggering of the default option
 6 #+ even if the variable is null.
8 username0=
9 echo "username0 has been declared, but is set to null."
10 echo "username0 = ${username0-`whoami`}"
11 # Will not echo.
12
13 echo
15 echo usernamel has not been declared.
16 echo "username1 = ${username1-`whoami`}"
17 # Will echo.
18
19 username2=
20 echo "username2 has been declared, but is set to null."
21 echo "username2 = ${username2:-`whoami`}"
23 # Will echo because of :- rather than just - in condition test.
24 # Compare to first instance, above.
25
26
27 #
28
29 # Once again:
30
31 variable=
32 # variable has been declared, but is set to null.
34 echo "${variable-0}" # (no output)
```

```
35 echo "${variable:-1}" # 1
36 # ^
37
38 unset variable
39
40 echo "${variable-2}" # 2
41 echo "${variable:-3}" # 3
42
43 exit 0
```

The default parameter construct finds use in providing "missing" command-line arguments in scripts.

```
1 DEFAULT_FILENAME=generic.data
2 filename=${1:-$DEFAULT_FILENAME}
3 # If not otherwise specified, the following command block operates
4 #+ on the file "generic.data".
5 #
6 # Commands follow.
```

See also Example 3-4, Example 28-2, and Example A-6.

Compare this method with <u>using an and list</u> to <u>supply a default command-line argument</u>. \${parameter=default}, \${parameter:=default}

If parameter not set, set it to *default*.

Both forms nearly equivalent. The: makes a difference only when \$parameter has been declared and is null, [1] as above.

```
1 echo ${username=`whoami`}
2 # Variable "username" is now set to `whoami`.
```

\${parameter+alt_value}, \${parameter:+alt_value}

If parameter set, use **alt_value**, else use null string.

Both forms nearly equivalent. The: makes a difference only when parameter has been declared and is null, see below.

```
1 echo "##### \${parameter+alt_value} #######"
2 echo
4 a=\$\{param1+xyz\}
                 # a =
5 echo "a = $a"
7 param2=
8 a=\$\{param2+xyz\}
9 echo "a = $a"
                 \# a = xyz
10
11 param3=123
12 a=${param3+xyz}
13 echo "a = $a"
                 \# a = xyz
14
15 echo
16 echo "##### \${parameter:+alt_value} #######"
19 a=${param4:+xyz}
21
22 param5=
23 a=${param5:+xyz}
25 # Different result from a=${param5+xyz}
```

```
27 param6=123
28 a=${param6:+xyz}
29 echo "a = $a"  # a = xyz
```

\${parameter?err_msg}, \${parameter:?err_msg}

If parameter set, use it, else print err_msg.

Both forms nearly equivalent. The : makes a difference only when parameter has been declared and is null, as above.

Example 9-16. Using parameter substitution and error messages

```
1 #!/bin/bash
 3 # Check some of the system's environmental variables.
     This is good preventative maintenance.
 5 # If, for example, $USER, the name of the person at the console, is not set,
 6 #+ the machine will not recognize you.
 8 : ${HOSTNAME?} ${USER?} ${HOME?} ${MAIL?}
 9
    echo
10 echo "Name of the machine is $HOSTNAME."
   echo "You are $USER."
11
12 echo "Your home directory is $HOME."
13 echo "Your mail INBOX is located in $MAIL."
14
15 echo "If you are reading this message,"
   echo "critical environmental variables have been set."
17
   echo
18
   echo
19
20 # ----
22 # The ${variablename?} construction can also check
23 #+ for variables set within the script.
25 ThisVariable=Value-of-ThisVariable
26 # Note, by the way, that string variables may be set
27 #+ to characters disallowed in their names.
28 : ${ThisVariable?}
29 echo "Value of ThisVariable is $ThisVariable".
30 echo
31 echo
32
33
34 : ${ZZXy23AB?"ZZXy23AB has not been set."}
35 # If ZZXy23AB has not been set,
36 #+ then the script terminates with an error message.
38 # You can specify the error message.
39 # : ${variablename?"ERROR MESSAGE"}
40
41
42 # Same result with:
                         dummy_variable=${ZZXy23AB?}
                         dummy_variable=${ZZXy23AB?"ZXy23AB has not been set."}
43 #
44 #
45 #
                         echo ${ZZXy23AB?} >/dev/null
47 # Compare these methods of checking whether a variable has been set
48 #+ with "set -u" . . .
49
50
51
52 echo "You will not see this message, because script already terminated."
```

```
53
54 HERE=0
55 exit $HERE  # Will NOT exit here.
56
57 # In fact, this script will return an exit status (echo $?) of 1.
```

Example 9-17. Parameter substitution and "usage" messages

Parameter substitution and/or expansion. The following expressions are the complement to the **match** in **expr** string operations (see Example 15-9). These particular ones are used mostly in parsing file path names.

Variable length / Substring removal

\${#var}

String length (number of characters in \$var). For an <u>array</u>, \${#array} is the length of the first element in the array.

\$\{\pmu\} and \$\{\pmu\} give the *number of positional parameters*.

♦ For an array, \${#array[*]} and \${#array[@]} give the number of elements in the array.

Example 9-18. Length of a variable

```
1 #!/bin/bash
2 # length.sh
3
4 E_NO_ARGS=65
5
6 if [ $# -eq 0 ] # Must have command-line args to demo script.
7 then
8 echo "Please invoke this script with one or more command-line arguments."
9 exit $E_NO_ARGS
10 fi
11
12 var01=abcdEFGH28ij
13 echo "var01 = ${var01}"
```

```
14 echo "Length of var01 = ${#var01}"

15 # Now, let's try embedding a space.

16 var02="abcd EFGH28ij"

17 echo "var02 = ${var02}"

18 echo "Length of var02 = ${#var02}"

19

20 echo "Number of command-line arguments passed to script = ${#@}"

21 echo "Number of command-line arguments passed to script = ${##}"

22

23 exit 0
```

\${var#Pattern}, \${var##Pattern}

\${var#Pattern} Remove from \$var the *shortest* part of \$Pattern that matches the *front* end of \$var.

\${var##Pattern} Remove from \$var the *longest* part of \$Pattern that matches the *front end* of \$var.

A usage illustration from Example A-7:

Manfred Schwarb's more elaborate variation of the above:

Another usage illustration:

```
1 echo `basename $PWD`
                               # Basename of current working directory.
2 echo "${PWD##*/}"
                              # Basename of current working directory.
3 echo
4 echo `basename $0`
                              # Name of script.
5 echo $0
                              # Name of script.
6 echo "${0##*/}"
                              # Name of script.
7 echo
8 filename=test.data
9 echo "${filename##*.}"
                               # data
10
                               # Extension of filename.
```

\${var%Pattern}, \${var%%Pattern}

\$var%Pattern} Remove from \$var the *shortest* part of \$Pattern that matches the *back* end of \$var.

\$var%%Pattern} Remove from \$var the *longest* part of \$Pattern that matches the *back* end of \$var.

Example 9-19. Pattern matching in parameter substitution

```
1 #!/bin/bash
2 # patt-matching.sh
4 # Pattern matching using the # ## % %% parameter substitution operators.
6 var1=abcd12345abc6789
7 pattern1=a*c # * (wild card) matches everything between a - c.
9 echo
10 echo "var1 = $var1"
                              # abcd12345abc6789
11 echo "var1 = ${var1}"
                              # abcd12345abc6789
                              # (alternate form)
13 echo "Number of characters in ${var1} = ${#var1}"
14 echo
15
16 echo "pattern1 = $pattern1"  # a*c (everything between 'a' and 'c')
17 echo "-----"
18 echo '${var1#$pattern1} = ' "${var1#$pattern1}"
                                                 #
                                                           d12345abc6789
19 # Shortest possible match, strips out first 3 characters abcd12345abc6789
21 echo '${var1##$pattern1} = ' "${var1##$pattern1}" #
                                                                   6789
22 # Longest possible match, strips out first 12 characters abcd12345abc6789
                                     ^^^^
23 #
                                                       |----|
24
25 echo; echo; echo
26
27 pattern2=b*9  # everything between 'b' and '9'
28 echo "var1 = $var1"  # Still abcd12345abc6789
30 echo "pattern2 = $pattern2"
31 echo "----"
33 # Shortest possible match, strips out last 6 characters abcd12345abc6789
34 #
35 echo '${var1%%pattern2} = ' "${var1%%$pattern2}" # a
36 # Longest possible match, strips out last 12 characters abcd12345abc6789
37 #
                                                        |----|
38
39 # Remember, # and ## work from the left end (beginning) of string,
40 # % and %% work from the right end.
41
42 echo
43
44 exit 0
```

Example 9-20. Renaming file extensions:

```
1 #!/bin/bash
2 # rfe.sh: Renaming file extensions.
3 #
4 # rfe old_extension new_extension
5 #
6 # Example:
7 # To rename all *.gif files in working directory to *.jpg,
8 # rfe gif jpg
9
```

```
10
11 E_BADARGS=65
12
13 case $# in
                     # The vertical bar means "or" in this context.
15 echo "Usage: `basename $0` old_file_suffix new_file_suffix"
   exit $E_BADARGS # If 0 or 1 arg, then bail out.
16
17 ;;
18 esac
19
2.0
21 for filename in *.$1
22 # Traverse list of files ending with 1st argument.
23 do
   mv $filename ${filename%$1}$2
    # Strip off part of filename matching 1st argument,
   #+ then append 2nd argument.
27 done
28
29 exit 0
```

Variable expansion / Substring replacement

These constructs have been adopted from ksh.

\${var:pos}

Variable var expanded, starting from offset pos.

\${var:pos:len}

Expansion to a max of *len* characters of variable *var*, from offset *pos*. See Example A-14 for an example of the creative use of this operator.

\${var/Pattern/Replacement}

First match of Pattern, within var replaced with Replacement.

If Replacement is omitted, then the first match of Pattern is replaced by nothing, that is, deleted.

\${var//Pattern/Replacement}

Global replacement. All matches of *Pattern*, within *var* replaced with *Replacement*.

As above, if Replacement is omitted, then all occurrences of Pattern are replaced by nothing, that is, deleted.

Example 9-21. Using pattern matching to parse arbitrary strings

```
1 #!/bin/bash
 3 var1=abcd-1234-defg
 4 echo "var1 = $var1"
 6 t=\${var1}*-*
 7 echo "var1 (with everything, up to and including first - stripped out) = $t"
 8 # t=${var1}*-} works just the same,
 9 #+ since # matches the shortest string,
10 #+ and * matches everything preceding, including an empty string.
11 # (Thanks, Stephane Chazelas, for pointing this out.)
13 t=${var1##*-*}
14 echo "If var1 contains a \"-\", returns empty string... var1 = $t"
15
16
17 t=${var1%*-*}
18 echo "var1 (with everything from the last - on stripped out) = $t"
19
```

```
20 echo
2.1
23 path_name=/home/bozo/ideas/thoughts.for.today
25 echo "path_name = $path_name"
26 t=${path_name##/*/}
27 echo "path_name, stripped of prefixes = $t"
28 # Same effect as t=`basename $path_name` in this particular case.
29 # t=\{path_name\%/\}; t=\{t\#\#*/\} is a more general solution,
30 #+ but still fails sometimes.
31 # If $path_name ends with a newline, then `basename $path_name` will not work,
32 #+ but the above expression will.
33 # (Thanks, S.C.)
34
35 t=${path_name%/*.*}
36 # Same effect as t=`dirname $path_name`
37 echo "path_name, stripped of suffixes = $t"
38 # These will fail in some cases, such as "../", "/foo////", # "foo/", "/".
39 # Removing suffixes, especially when the basename has no suffix,
40 #+ but the dirname does, also complicates matters.
41 # (Thanks, S.C.)
42
43 echo
44
45 t=${path_name:11}
46 echo "$path_name, with first 11 chars stripped off = $t"
47 t=${path_name:11:5}
48 echo "$path_name, with first 11 chars stripped off, length 5 = $t"
49
50 echo
51
52 t=${path_name/bozo/clown}
53 echo "$path_name with \"bozo\" replaced by \"clown\" = $t"
54 t=${path_name/today/}
55 echo "$path_name with \"today\" deleted = $t"
56 t=${path_name//o/0}
57 echo "$path_name with all o's capitalized = $t"
58 t=${path_name//o/}
59 echo "$path_name with all o's deleted = $t"
60
61 exit 0
```

\${var/#Pattern/Replacement}

If *prefix* of var matches Pattern, then substitute Replacement for Pattern.

\${var/%Pattern/Replacement}

If suffix of var matches Pattern, then substitute Replacement for Pattern.

Example 9-22. Matching patterns at prefix or suffix of string

```
1 #!/bin/bash
2 # var-match.sh:
3 # Demo of pattern replacement at prefix / suffix of string.
4
5 v0=abc1234zip1234abc # Original variable.
6 echo "v0 = $v0" # abc1234zip1234abc
7 echo
8
9 # Match at prefix (beginning) of string.
10 v1=${v0/#abc/ABCDEF} # abc1234zip1234abc
11 # |-|
12 echo "v1 = $v1" # ABCDEF1234zip1234abc
```

```
13
                            # |----|
14
15 # Match at suffix (end) of string.
16 v2=${v0/%abc/ABCDEF} # abc1234zip123abc
                                           |-|
18 echo "v2 = $v2"
                            # abc1234zip1234ABCDEF
19
                                            |----|
20
21 echo
22
23 #
24 # Must match at beginning / end of string,
25 #+ otherwise no replacement results.
27 v3=\{v0/\#123/000\} # Matches, but not at beginning. 28 echo "v3 = v3" # abc1234zip1234abc
29
                            # NO REPLACEMENT.
30 v4=${v0/%123/000}
                            # Matches, but not at end.
31 echo "v4 = $v4"
                            # abc1234zip1234abc
32
                            # NO REPLACEMENT.
33
34 exit 0
```

\${!varprefix*},\${!varprefix@}

Matches *names* of all previously declared variables beginning with *varprefix*.

```
1 xyz23=whatever
2 xyz24=
3
4 a=${!xyz*}  # Expands to *names* of declared variables beginning with "xyz".
5 echo "a = $a"  # a = xyz23 xyz24
6 a=${!xyz@}  # Same as above.
7 echo "a = $a"  # a = xyz23 xyz24
8
9 # Bash, version 2.04, adds this feature.
```

Notes

<u>Prev</u>

[1] If \$parameter is null in a non-interactive script, it will terminate with a 127 exit status (the Bash error code for "command not found").

Manipulating Strings Up Typing variables: declare or typeset

Advanced Book Sovinting Children An in death explanation of the art of shell scripting

Advanced Bash-Scripting Guide: An in-depth exploration of the art of shell scripting Chapter 9. Variables Revisited

<u>Next</u>

9.4. Typing variables: declare or typeset

The *declare* or *typeset* <u>builtins</u> (they are exact synonyms) permit restricting the properties of variables. This is a very weak form of the typing available in certain programming languages. The **declare** command is specific to version 2 or later of Bash. The **typeset** command also works in ksh scripts.

declare/typeset options

-r readonly

```
1 declare -r var1
(declare -r var1 works the same as readonly var1)
```

This is the rough equivalent of the C **const** type qualifier. An attempt to change the value of a readonly variable fails with an error message.

-i integer

```
1 declare -i number
2 # The script will treat subsequent occurrences of "number" as an integer.
3
4 number=3
5 echo "Number = $number" # Number = 3
6
7 number=three
8 echo "Number = $number" # Number = 0
9 # Tries to evaluate the string "three" as an integer.
```

Certain arithmetic operations are permitted for declared integer variables without the need for <u>expr</u> or <u>let</u>.

```
1 n=6/3
2 echo "n = $n"  # n = 6/3
3
4 declare -i n
5 n=6/3
6 echo "n = $n"  # n = 2
```

-a array

```
1 declare -a indices
```

The variable indices will be treated as an array.

-f function(s)

```
1 declare -f
```

A **declare -f** line with no arguments in a script causes a listing of all the <u>functions</u> previously defined in that script.

```
1 declare -f function_name
```

A declare -f function_name in a script lists just the function named.

-x export

```
1 declare -x var3
```

This declares a variable as available for exporting outside the environment of the script itself. -x var=\$value

```
1 declare -x var3=373
```

The **declare** command permits assigning a value to a variable in the same statement as setting its properties.

Example 9-23. Using *declare* to type variables

```
1 #!/bin/bash
2
3 func1 ()
5 echo This is a function.
8 declare -f # Lists the function above.
9
10 echo
11
12 declare -i var1 # var1 is an integer.
13 var1=2367
14 echo "var1 declared as $var1"
15 var1=var1+1  # Integer declaration eliminates the need for 'let'.
16 echo "var1 incremented by 1 is $var1."
17 # Attempt to change variable declared as integer.
18 echo "Attempting to change var1 to floating point value, 2367.1."
19 var1=2367.1  # Results in error message, with no change to variable.
20 echo "var1 is still $var1"
21
22 echo
23
24 declare -r var2=13.36  # 'declare' permits setting a variable property
                                #+ and simultaneously assigning it a value.
26 echo "var2 declared as $var2" # Attempt to change readonly variable.
27 var2=13.37
                                # Generates error message, and exit from script.
28
29 echo "var2 is still $var2"  # This line will not execute.
31 exit 0
                                # Script will not exit here.
```

1 Using the *declare* builtin restricts the scope of a variable.

```
1 foo ()
2 {
3 FOO="bar"
4 }
5
6 bar ()
7 {
8 foo
9 echo $FOO
10 }
11
12 bar # Prints bar.
```

However . . .

```
1 foo () {
2 declare FOO="bar"
3 }
4
5 bar ()
6 {
7 foo
8 echo $FOO
```

```
9 }
10
11 bar # Prints nothing.
14 # Thank you, Michael Iatrou, for pointing this out.
```

<u>Prev</u> **Home** <u>Next</u> Parameter Substitution <u>Up</u> Indirect References

Advanced Bash-Scripting Guide: An in-depth exploration of the art of shell scripting

Chapter 9. Variables Revisited <u>Prev</u> <u>Next</u>

9.5. Indirect References

Assume that the value of a variable is the name of a second variable. Is it somehow possible to retrieve the value of this second variable from the first one? For example, if $a=letter_of_alphabet$ and $letter_of_alphabet=z$, can a reference to a return z? This can indeed be done, and it is called an indirect reference. It uses the unusual eval $var1=\$ \$\$var2\$ notation.

Example 9-24. Indirect Variable References

```
1 #!/bin/bash
 2 # ind-ref.sh: Indirect variable referencing.
 3 # Accessing the contents of the contents of a variable.
5 a=letter_of_alphabet # Variable "a" holds the name of another variable.
 6 letter_of_alphabet=z
7
8 echo
10 # Direct reference.
                          # a = letter_of_alphabet
11 echo "a = $a"
12
13 # Indirect reference.
14 eval a=\$$a
15 echo "Now a = $a"  # Now a = z
17 echo
18
19
20 # Now, let's try changing the second-order reference.
2.1
22 t=table_cell_3
23 table_cell_3=24
24 echo "\"table_cell_3\" = \frac{3}{3} # "table_cell_3" = 24 25 echo -n "dereferenced \"t\" = "; eval echo \$$t # dereferenced "t" = 24
26 # In this simple case, the following also works (why?).
27 #
        eval t=\$$t; echo "\"t\" = $t"
2.8
29 echo
31 t=table cell 3
32 NEW_VAL=387
33 table_cell_3=$NEW_VAL
34 echo "Changing value of \"table_cell_3\" to $NEW_VAL."
35 echo "\"table_cell_3\" now $table_cell_3"
36 echo -n "dereferenced \"t\" now "; eval echo \$$t
37 \# "eval" takes the two arguments "echo" and "\$$t" (set equal to $table_cell_3)
39 echo
41 # (Thanks, Stephane Chazelas, for clearing up the above behavior.)
42
4.3
44 # Another method is the ${!t} notation, discussed in "Bash, version 2" section.
45 # See also ex78.sh.
47 exit 0
```

Of what practical use is indirect referencing of variables? It gives Bash a little of the functionality of *pointers* in C, for instance, in <u>table lookup</u>. And, it also has some other very interesting applications. . . .

Nils Radtke shows how to build "dynamic" variable names and evaluate their contents. This can be useful when <u>sourcing</u> configuration files.

```
1 #!/bin/bash
2
 3
 5 # This could be "sourced" from a separate file.
 6 isdnMyProviderRemoteNet=172.16.0.100
 7 isdnYourProviderRemoteNet=10.0.0.10
8 isdnOnlineService="MyProvider"
9 # -----
10
11
12 remoteNet=$(eval "echo \$$(echo isdn${isdnOnlineService}RemoteNet)")
13 remoteNet=$(eval "echo \$$(echo isdnMyProviderRemoteNet)")
14 remoteNet=$(eval "echo \$isdnMyProviderRemoteNet")
15 remoteNet=$(eval "echo $isdnMyProviderRemoteNet")
17 echo "$remoteNet" # 172.16.0.100
18
20
21 # And, it gets even better.
22
23 # Consider the following snippet given a variable named getSparc,
24 #+ but no such variable getIa64:
25
26 chkMirrorArchs () {
27 arch="$1";
   if [ "$(eval "echo \${$(echo get$(echo -ne $arch |
28
   sed 's/^\(.\).*/\1/g' | tr 'a-z' 'A-Z'; echo $arch |
29
30
        sed 's/^.\(.*\)/\1/g')):-false}")" = true ]
31 then
32 return 0;
33 else
34 return 1;
35 fi;
36 }
37
38 getSparc="true"
39 unset getIa64
40 chkMirrorArchs sparc
41 echo $? # 0
42 # True
43
44 chkMirrorArchs Ia64
45 echo $?  # 1
46  # False
46
47
48 # Notes:
49 # ----
50 # Even the to-be-substituted variable name part is built explicitly.
51 # The parameters to the chkMirrorArchs calls are all lower case.
52 # The variable name is composed of two parts: "get" and "Sparc" . . .
```

Example 9-25. Passing an indirect reference to awk

```
1 #!/bin/bash
2
3 # Another version of the "column totaler" script
4 #+ that adds up a specified column (of numbers) in the target file.
5 # This one uses indirect references.
```

```
7 ARGS=2
 8 E_WRONGARGS=65
10 if [ $# -ne "$ARGS" ] # Check for proper no. of command line args.
    echo "Usage: `basename $0` filename column-number"
12
13 exit $E WRONGARGS
14 fi
15
16 filename=$1
17 column_number=$2
19 #==== Same as original script, up to this point =====#
20
22 # A multi-line awk script is invoked by awk ' ..... '
23
24
25 # Begin awk script.
26 # -----
27 awk "
28
29 { total += \$${column_number} # indirect reference
31 END {
32 print total
3.3
       }
34
      " "$filename"
35
36 # -----
37 # End awk script.
38
39 # Indirect variable reference avoids the hassles
40 \#+ of referencing a shell variable within the embedded awk script.
41 # Thanks, Stephane Chazelas.
44 exit 0
```

This method of indirect referencing is a bit tricky. If the second order variable changes its value, then the first order variable must be properly dereferenced (as in the above example). Fortunately, the \${!variable} notation introduced with version 2 of Bash (see Example 34-2 and Example A-24) makes indirect referencing more intuitive.

Bash does not support pointer arithmetic, and this severely limits the usefulness of indirect referencing. In fact, indirect referencing in a scripting language is, at best, an ugly kludge.

Typing variables: declare or typeset Up \$RANDOM: generate random integer

Advanced Bash-Scripting Guide: An in-depth exploration of the art of shell scripting

Prev Chapter 9. Variables Revisited

<u>Next</u>

9.6. \$RANDOM: generate random integer

\$RANDOM is an internal Bash <u>function</u> (not a constant) that returns a <u>pseudorandom</u> [1] integer in the range 0 - 32767. It should <u>not</u> be used to generate an encryption key.

Example 9-26. Generating random numbers

```
1 #!/bin/bash
 3 # $RANDOM returns a different random integer at each invocation.
4 # Nominal range: 0 - 32767 (signed 16-bit integer).
 6 MAXCOUNT=10
7 count=1
8
9 echo
10 echo "$MAXCOUNT random numbers:"
11 echo "-----"
12 while [ "$count" -le $MAXCOUNT ] # Generate 10 ($MAXCOUNT) random integers.
13 do
   number=$RANDOM
15
    echo $number
16 let "count += 1" # Increment count.
17 done
18 echo "-----"
19
20 # If you need a random int within a certain range, use the 'modulo' operator.
21 # This returns the remainder of a division operation.
23 RANGE=500
24
25 echo
27 number=$RANDOM
28 let "number %= $RANGE"
30 echo "Random number less than $RANGE --- $number"
31
32 echo
33
34
36 \# If you need a random integer greater than a lower bound,
37 #+ then set up a test to discard all numbers below that.
38
39 FLOOR=200
41 number=0 #initialize
42 while [ "$number" -le $FLOOR ]
43 do
44 number=$RANDOM
45 done
46 echo "Random number greater than $FLOOR --- $number"
47 echo
48
49 # Let's examine a simple alternative to the above loop, namely
50 # let "number = $RANDOM + $FLOOR"
# That would eliminate the while-loop and run faster.
52 # But, there might be a problem with that. What is it?
53
54
```

```
55
 56 # Combine above two techniques to retrieve random number between two limits.
 57 number=0 #initialize
 58 while [ "$number" -le $FLOOR ]
 60 number=$RANDOM
 61 let "number %= $RANGE" # Scales $number down within $RANGE.
 63 echo "Random number between $FLOOR and $RANGE --- $number"
 64 echo
 65

Example 9-28. Brownian Motion Simulation

```
1 #!/bin/bash
 2 # brownian.sh
 3 # Author: Mendel Cooper
 4 # Reldate: 10/26/07
 5 # License: GPL3
 7 #
 8 # This script models Brownian motion:
9 #+ the random wanderings of tiny particles in a fluid,
10 #+ as they are impacted by random currents and collisions.
11 #+ This is colloquially known as the "Drunkard's Walk."
13 # It can also be considered as a stripped-down simulation of a
14 #+ Galton Board, a slanted board with a pattern of pegs,
15 #+ down which rolls a succession of marbles, one at a time.
16 #+ At the bottom is a row of slots or catch basins in which
17 #+ the marbles finally come to rest.
18 # Think of it as a kind of bare-bones Pachinko game.
19 # As you see by running the script,
```

```
20 #+ most of the marbles cluster around the center slot.
21 \#+ This is consistent with the expected binomial distribution.
22 # As a Galton Board simulation, the script
23 #+ disregards such parameters as
24 #+ board tilt-angle, rolling friction of the marbles,
25 #+ angles of impact, and elasticity of the pegs.
26 # Does this affect the accuracy of the simulation?
27 # -
28

110 # Exercises:
111 # -----
112 # 1) Show the results in a vertical bar graph, or as an alternative,
113 #+ a scattergram.
114 # 2) Alter the script to use /dev/urandom instead of $RANDOM.
115 # Will this make the results more random?
```

Jipe points out a set of techniques for generating random numbers within a range.

```
1 # Generate random number between 6 and 30.
2     rnumber=$((RANDOM%25+6))
3
4 # Generate random number in the same 6 - 30 range,
5 #+ but the number must be evenly divisible by 3.
6     rnumber=$(((RANDOM%30/3+1)*3))
7
8 # Note that this will not work all the time.
9 # It fails if $RANDOM%30 returns 0.
10
11 # Frank Wang suggests the following alternative:
12     rnumber=$((RANDOM%27/3*3+6))
```

Bill Gradwohl came up with an improved formula that works for positive numbers.

```
1 rnumber=$(((RANDOM%(max-min+divisibleBy))/divisibleBy*divisibleBy+min))
Here Bill presents a versatile function that returns a random number between two specified values.
```

Example 9-29. Random between values

```
1 #!/bin/bash
2 # random-between.sh
3 # Random number between two specified values.
4 # Script by Bill Gradwohl, with minor modifications by the document author.
5 # Used with permission.
6
7
8 randomBetween() {
9 # Generates a positive or negative random number
10 #+ between $min and $max
```

```
11
     #+ and divisible by $divisibleBy.
12
     # Gives a "reasonably random" distribution of return values.
1.3

Just how random is \$RANDOM? The best way to test this is to write a script that tracks the distribution of "random" numbers generated by \$RANDOM. Let's roll a \$RANDOM die a few times . . .

Example 9-30. Rolling a single die with RANDOM

```
1 #!/bin/bash
2 # How random is RANDOM?
3
4 RANDOM=$$ # Reseed the random number generator using script process ID.
5
6 PIPS=6 # A die has 6 pips.
```

```
7 MAXTHROWS=600  # Increase this if you have nothing better to do with your time.
8 throw=0 # Throw count.
9
10 ones=0
                  # Must initialize counts to zero,
                 #+ since an uninitialized variable is null, not zero.
12 threes=0
13 fours=0
14 fives=0
15 sixes=0
16
17 print_result ()
18 {
19 echo
20 echo "ones = $ones"
21 echo "twos = $twos"
22 echo "threes = $threes"
23 echo "fours = $fours"
24 echo "fives = $fives"
25 echo "sixes = $sixes"
26 echo
27 }
28
29 update_count()
30 {
31 case "$1" in
32 0) let "ones += 1";;  # Since die has no "zero", this corresponds to 1.
33 1) let "twos += 1";;  # And this to 2, etc.
34 2) let "threes += 1";;
35 3) let "fours += 1";;
36 4) let "fives += 1";;
37 5) let "sixes += 1";;
38 esac
39 }
4.0
41 echo
42
4.3
44 while [ "$throw" -lt "$MAXTHROWS" ]
46 let "die1 = RANDOM % $PIPS"
   update_count $die1
47
48 let "throw += 1"
49 done
50
51 print_result
52
53 exit 0
55 # The scores should distribute fairly evenly, assuming RANDOM is fairly random.
56 \ \# With $MAXTHROWS at 600, all should cluster around 100, plus-or-minus 20 or so.
58 # Keep in mind that RANDOM is a pseudorandom generator,
59 #+ and not a spectacularly good one at that.
60
61 # Randomness is a deep and complex subject.
62 # Sufficiently long "random" sequences may exhibit
63 #+ chaotic and other "non-random" behavior.
64
65 # Exercise (easy):
66 # -----
67 # Rewrite this script to flip a coin 1000 times.
68 # Choices are "HEADS" and "TAILS".
```

As we have seen in the last example, it is best to *reseed* the *RANDOM* generator each time it is invoked. Using the same seed for *RANDOM* repeats the same series of numbers. [2] (This mirrors the behavior of the

Example 9-31. Reseeding RANDOM

```
1 #!/bin/bash
 2 # seeding-random.sh: Seeding the RANDOM variable.
 4 MAXCOUNT=25
                # How many numbers to generate.
6 random_numbers ()
7 {
8 count=0
9 while [ "$count" -lt "$MAXCOUNT" ]
10 do
   number=$RANDOM
11
12 echo -n "$number "
13 let "count += 1"
14 done
15 }
16
17 echo; echo
18
19 RANDOM=1
                   # Setting RANDOM seeds the random number generator.
20 random_numbers
21
22 echo; echo
23
24 RANDOM=1
                    # Same seed for RANDOM...
25 random_numbers # ...reproduces the exact same number series.
26
27
                    # When is it useful to duplicate a "random" number series?
28
29 echo; echo
30
31 RANDOM=2
                   # Trying again, but with a different seed...
32 random_numbers # gives a different number series.
33
34 echo; echo
3.5
36 # RANDOM=$$ seeds RANDOM from process id of script.
37 # It is also possible to seed RANDOM from 'time' or 'date' commands.
38
39 # Getting fancy...
40 SEED=$(head -1 /dev/urandom | od -N 1 | awk '{ print $2 }')
41 # Pseudo-random output fetched
42 #+ from /dev/urandom (system pseudo-random device-file),
43 #+ then converted to line of printable (octal) numbers by "od",
44 #+ finally "awk" retrieves just one number for SEED.
45 RANDOM=$SEED
46 random_numbers
47
48 echo; echo
49
50 exit 0
```

The /dev/urandom pseudo-device file provides a method of generating much more "random" pseudorandom numbers than the \$RANDOM variable. dd if=/dev/urandom of=targetfile bs=1 count=XX creates a file of well-scattered pseudorandom numbers. However, assigning these numbers to a variable in a script requires a workaround, such as filtering through od (as in above example, Example 15-14, and Example A-38), or using dd (see Example 15-58), or even piping to

There are also other ways to generate pseudorandom numbers in a script. **Awk** provides a convenient means of doing this.

Example 9-32. Pseudorandom numbers, using awk

```
1 #!/bin/bash
 2 # random2.sh: Returns a pseudorandom number in the range 0 - 1.
 3 # Uses the awk rand() function.
 5 AWKSCRIPT=' { srand(); print rand() } '
              Command(s) / parameters passed to awk
 7 # Note that srand() reseeds awk's random number generator.
10 echo -n "Random number between 0 and 1 = "
12 echo | awk "$AWKSCRIPT"
13 # What happens if you leave out the 'echo'?
15 exit 0
16
17
18 # Exercises:
19 # -----
20
21 # 1) Using a loop construct, print out 10 different random numbers.
22 # (Hint: you must reseed the "srand()" function with a different seed
23 #+
        in each pass through the loop. What happens if you fail to do this?)
25 # 2) Using an integer multiplier as a scaling factor, generate random numbers
26 #+ in the range between 10 and 100.
27
28 # 3) Same as exercise #2, above, but generate random integers this time.
```

The <u>date</u> command also lends itself to <u>generating pseudorandom integer sequences</u>.

Notes

- [1] True "randomness," insofar as it exists at all, can only be found in certain incompletely understood natural phenomena such as radioactive decay. Computers can only simulate randomness, and computer-generated sequences of "random" numbers are therefore referred to as *pseudorandom*.
- [2] The *seed* of a computer-generated pseudorandom number series can be considered an identification label. For example, think of the pseudorandom series with a seed of 23 as *series #23*.

A property of a pseurandom number series is the length of the cycle before it starts repeating itself. A good pseurandom generator will produce series with very long cycles.

9.7. The Double Parentheses Construct

Similar to the <u>let</u> command, the ((...)) construct permits arithmetic expansion and evaluation. In its simplest form, a=\$((5+3)) would set a to 5+3, or 8. However, this double parentheses construct is also a mechanism for allowing C-style manipulation of variables in Bash, for example, ((var++)).

Example 9-33. C-style manipulation of variables

```
1 #!/bin/bash
 2 # Manipulating a variable, C-style, using the ((...)) construct.
4
5 echo
7 (( a = 23 )) # Setting a value, C-style,
             #+ with spaces on both sides of the "=".
9 echo "a (initial value) = $a"
10
11 ((a++)) # Post-increment 'a', C-style.
12 echo "a (after a++) = $a"
14 ((a--)) # Post-decrement 'a', C-style.
15 echo "a (after a--) = $a"
16
18 (( ++a ))  # Pre-increment 'a', C-style.
19 echo "a (after ++a) = a"
2.0
21 (( --a ))
             # Pre-decrement 'a', C-style.
22 echo "a (after --a) = $a"
23
24 echo
27 # Note that, as in C, pre- and post-decrement operators
28 #+ have slightly different side-effects.
30 n=1; let --n && echo "True" || echo "False" # False
31 n=1; let n-- && echo "True" || echo "False" # True
33 # Thanks, Jeroen Domburg.
3.5
36 echo
37
38 (( t = a<45?7:11 )) # C-style trinary operator.
        ^ ^ ^
40 echo "If a < 45, then t = 7, else t = 11."
41 echo "t = $t " # Yes!
42
43 echo
44
4.5
46 # -----
47 # Easter Egg alert!
48 # -----
49 # Chet Ramey seems to have snuck a bunch of undocumented C-style
50 #+ constructs into Bash (actually adapted from ksh, pretty much).
51 # In the Bash docs, Ramey calls ((...)) shell arithmetic,
```

```
52 #+ but it goes far beyond that.
53 # Sorry, Chet, the secret is now out.
54
55 # See also "for" and "while" loops using the ((...)) construct.
56
57 # These work only with Bash, version 2.04 or later.
58
59 exit 0
```

See also Example 10-12 and Example 8-4.

RANDOM: generate random \underline{Up} Loops and Branches

integer

Advanced Bash-Scripting Guide: An in-depth exploration of the art of shell scripting

<u>Prev</u> <u>Next</u>

Chapter 10. Loops and Branches

What needs this iteration, woman?

--Shakespeare, Othello

Operations on code blocks are the key to structured and organized shell scripts. Looping and branching constructs provide the tools for accomplishing this.

10.1. Loops

A *loop* is a block of code that *iterates* [1] a list of commands as long as the *loop control condition* is true.

for loops

for argin [list]

This is the basic looping construct. It differs significantly from its C counterpart.

```
for arg in [list]
do
  command(s)...
done
```

During each pass through the loop, arg takes on the value of each successive variable in the list.

```
1 for arg in "$var1" "$var2" "$var3" ... "$varN"
2 # In pass 1 of the loop, arg = $var1
3 # In pass 2 of the loop, arg = $var2
4 # In pass 3 of the loop, arg = $var3
5 # ...
6 # In pass N of the loop, arg = $varN
7
8 # Arguments in [list] quoted to prevent possible word splitting.
```

The argument list may contain wild cards.

If do is on same line as for, there needs to be a semicolon after list.

for arg in [list]; do

Example 10-1. Simple for loops

```
1 #!/bin/bash
 2 # Listing the planets.
 4 for planet in Mercury Venus Earth Mars Jupiter Saturn Uranus Neptune Pluto
 6 echo $planet # Each planet on a separate line.
 7 done
 8
 9 echo
10
11 for planet in "Mercury Venus Earth Mars Jupiter Saturn Uranus Neptune Pluto"
     # All planets on same line.
13
       # Entire 'list' enclosed in quotes creates a single variable.
       # Why? Whitespace incorporated into the variable.
14
15 do
16 echo $planet
17 done
18
19 exit 0
```

Each [list] element may contain multiple parameters. This is useful when processing parameters in groups. In such cases, use the <u>set</u> command (see <u>Example 14-16</u>) to force parsing of each [list] element and assignment of each component to the positional parameters.

Example 10-2. for loop with two parameters in each [list] element

```
1 #!/bin/bash
 2 # Planets revisited.
 4 # Associate the name of each planet with its distance from the sun.
 6 for planet in "Mercury 36" "Venus 67" "Earth 93" "Mars 142" "Jupiter 483"
 7 do
 8 set -- $planet # Parses variable "planet"
                   #+ and sets positional parameters.
10 # The "--" prevents nasty surprises if $planet is null or
11 #+ begins with a dash.
12
13
    # May need to save original positional parameters,
14 #+ since they get overwritten.
15 # One way of doing this is to use an array,
16
     # original_params=("$@")
17
    echo "$1 $2,000,000 miles from the sun"
18
19
    #----two tabs---concatenate zeroes onto parameter $2
20 done
21
22 # (Thanks, S.C., for additional clarification.)
2.3
24 exit 0
```

A variable may supply the [list] in a *for loop*.

Example 10-3. Fileinfo: operating on a file list contained in a variable

```
1 #!/bin/bash
 2 # fileinfo.sh
 4 FILES="/usr/sbin/accept
5 /usr/sbin/pwck
 6 /usr/sbin/chroot
 7 /usr/bin/fakefile
8 /sbin/badblocks
9 /sbin/ypbind" # List of files you are curious about.
10
                  # Threw in a dummy file, /usr/bin/fakefile.
11
12 echo
13
14 for file in $FILES
15 do
16
   if [ ! -e "$file" ] # Check if file exists.
17
18
19
     echo "$file does not exist."; echo
20
                           # On to next.
21
22
23 ls -1 $file | awk '{ print $9 " file size: " $5 }' # Print 2 fields.
24 whatis `basename $file` # File info.
```

```
# Note that the whatis database needs to have been set up for this to work.

# To do this, as root run /usr/bin/makewhatis.

done

exit 0
```

If the [list] in a *for loop* contains wildcards (* and ?) used in filename expansion, then globbing takes place.

Example 10-4. Operating on files with a for loop

```
1 #!/bin/bash
 2 # list-glob.sh: Generating [list] in a for-loop, using "globbing"
 4 echo
 6 for file in *
 7 \ \# ^ Bash performs filename expansion
 8 #+
                 on expressions that globbing recognizes.
9 do
10 ls -l "$file" # Lists all files in $PWD (current directory).
11 # Recall that the wild card character "*" matches every filename,
12 #+ however, in "globbing," it doesn't match dot-files.
13
14 # If the pattern matches no file, it is expanded to itself.
15 # To prevent this, set the nullglob option
   #+ (shopt -s nullglob).
16
17 # Thanks, S.C.
18 done
19
20 echo; echo
2.1
22 for file in [jx]*
23 do
24 rm -f $file # Removes only files beginning with "j" or "x" in $PWD.
    echo "Removed file \"$file\"".
26 done
27
28 echo
29
30 exit 0
```

Omitting the **in** [list] part of a *for loop* causes the loop to operate on \$@ -- the <u>positional</u> <u>parameters</u>. A particularly clever illustration of this is <u>Example A-16</u>. See also <u>Example 14-17</u>.

Example 10-5. Missing in [list] in a for loop

```
1 #!/bin/bash
2
3 # Invoke this script both with and without arguments,
4 #+ and see what happens.
5
6 for a
7 do
8 echo -n "$a "
9 done
```

```
10
11 # The 'in list' missing, therefore the loop operates on '$@'
12 #+ (command-line argument list, including whitespace).
13
14 echo
15
16 exit 0
```

It is possible to use <u>command substitution</u> to generate the [list] in a *for loop*. See also <u>Example 15-52</u>, <u>Example 10-10</u> and <u>Example 15-46</u>.

Example 10-6. Generating the [list] in a for loop with command substitution

```
1 #!/bin/bash
2 # for-loopcmd.sh: for-loop with [list]
3 #+ generated by command substitution.
4
5 NUMBERS="9 7 3 8 37.53"
6
7 for number in `echo $NUMBERS` # for number in 9 7 3 8 37.53
8 do
9 echo -n "$number "
10 done
11
12 echo
13 exit 0
```

Here is a somewhat more complex example of using command substitution to create the [list].

Example 10-7. A grep replacement for binary files

```
1 #!/bin/bash
 2 # bin-grep.sh: Locates matching strings in a binary file.
 4 # A "grep" replacement for binary files.
 5 # Similar effect to "grep -a"
 6
 7 E_BADARGS=65
 8 E_NOFILE=66
 9
10 if [ $# -ne 2 ]
11 then
12 echo "Usage: `basename $0` search_string filename"
13 exit $E_BADARGS
14 fi
15
16 if [ ! -f "$2" ]
18 echo "File \"$2\" does not exist."
19 exit $E_NOFILE
20 fi
2.1
2.2
23 IFS=$'\012'
                    # Per suggestion of Anton Filippov.
                    # was: IFS="\n"
25 for word in $( strings "$2" | grep "$1")
26 # The "strings" command lists strings in binary files.
27 # Output then piped to "grep", which tests for desired string.
28 do
```

```
29 echo $word
30 done
31
32 # As S.C. points out, lines 23 - 30 could be replaced with the simpler
33 # strings "$2" | grep "$1" | tr -s "$IFS" '[\n*]'
34
35
36 # Try something like "./bin-grep.sh mem /bin/ls"
37 #+ to exercise this script.
38
39 exit 0
```

More of the same.

Example 10-8. Listing all users on the system

```
1 #!/bin/bash
 2 # userlist.sh
 4 PASSWORD_FILE=/etc/passwd
 5 n=1 # User number
 7 for name in $(awk 'BEGIN{FS=":"}{print $1}' < "$PASSWORD_FILE")
 8 # Field separator = : ^^^^^
                                  ^^^^
 9 # Print first field
                                              ^^^^^
10 # Get input from password file
12 echo "USER #$n = $name"
13 let "n += 1"
14 done
15
16
17 # USER #1 = root
18 # USER #2 = bin
19 # USER #3 = daemon
20 # ...
21 # USER #30 = bozo
22
23 exit 0
2.4
25 # Exercise:
27 # How is it that an ordinary user (or a script run by same)
28 #+ can read /etc/passwd?
29 # Isn't this a security hole? Why or why not?
```

A final example of the [list] resulting from command substitution.

Example 10-9. Checking all the binaries in a directory for authorship

```
1 #!/bin/bash
2 # findstring.sh:
3 # Find a particular string in the binaries in a specified directory.
4
5 directory=/usr/bin/
6 fstring="Free Software Foundation" # See which files come from the FSF.
7
8 for file in $( find $directory -type f -name '*' | sort )
9 do
10 strings -f $file | grep "$fstring" | sed -e "s%$directory%%"
```

```
# In the "sed" expression,

# it is necessary to substitute for the normal "/" delimiter

# because "/" happens to be one of the characters filtered out.

# Failure to do so gives an error message (try it).

done

exit 0

Exercise (easy):

# Convert this script to take command-line parameters

# for $directory and $fstring.
```

The output of a *for loop* may be piped to a command or commands.

Example 10-10. Listing the *symbolic links* in a directory

```
1 #!/bin/bash
 2 # symlinks.sh: Lists symbolic links in a directory.
 5 directory=${1-`pwd`}
 6 # Defaults to current working directory,
 7 #+ if not otherwise specified.
 8 # Equivalent to code block below.
10 # ARGS=1
                          # Expect one command-line argument.
11 #
12 # if [ $# -ne "$ARGS" ] # If not 1 arg...
13 # then
14 # directory=`pwd` # current working directory
15 # else
16 # directory=$1
17 # fi
18 # -----
20 echo "symbolic links in directory \"$directory\""
22 for file in "$( find $directory -type 1 )" # -type 1 = symbolic links
23 do
24 echo "$file"
25 done | sort
                                                # Otherwise file list is unsorted.
26 # Strictly speaking, a loop isn't really necessary here,
27 #+ since the output of the "find" command is expanded into a single word.
28 # However, it's easy to understand and illustrative this way.
29
30 # As Dominik 'Aeneas' Schnitzer points out,
31 #+ failing to quote $( find $directory -type 1 )
32 #+ will choke on filenames with embedded whitespace.
33 # Even this will only pick up the first field of each argument.
34
35 exit 0
36
37
39 # Jean Helou proposes the following alternative:
41 echo "symbolic links in directory \"$directory\""
42 # Backup of the current IFS. One can never be too cautious.
43 OLDIFS=$IFS
44 IFS=:
45
```

```
46 for file in $(find $directory -type 1 -printf "%p$IFS")
47 do #
        echo "$file"
48
49
        done|sort
51 # And, James "Mike" Conley suggests modifying Helou's code thusly:
52
53 OLDIFS=$IFS
54 IFS='' # Null IFS means no word breaks
55 for file in $( find $directory -type 1 )
56 do
57
   echo $file
   done | sort
58
59
60 \# This works in the "pathological" case of a directory name having
61 #+ an embedded colon.
     "This also fixes the pathological case of the directory name having
63 #+ a colon (or space in earlier example) as well."
64
```

The stdout of a loop may be <u>redirected</u> to a file, as this slight modification to the previous example shows.

Example 10-11. Symbolic links in a directory, saved to a file

```
1 #!/bin/bash
 2 # symlinks.sh: Lists symbolic links in a directory.
 4 OUTFILE=symlinks.list
                                              # save file
 6 directory=${1-`pwd`}
 7 # Defaults to current working directory,
 8 #+ if not otherwise specified.
10
11 echo "symbolic links in directory \"$directory\"" > "$OUTFILE"
12 echo "-----" >> "$OUTFILE"
14 for file in "$( find $directory -type 1 )" # -type 1 = symbolic links
15 do
16 echo "$file"
17 done | sort >> "$OUTFILE"
                                              # stdout of loop
                                                redirected to save file.
              ^^^^^
18 #
19
20 exit 0
```

There is an alternative syntax to a *for loop* that will look very familiar to C programmers. This requires <u>double parentheses</u>.

Example 10-12. A C-style for loop

```
1 #!/bin/bash
2 # Two ways to count up to 10.
3
4 echo
5
6 # Standard syntax.
7 for a in 1 2 3 4 5 6 7 8 9 10
```

```
8 do
9 echo -n "$a "
10 done
11
12 echo; echo
14 # +======+
15
16 # Now, let's do the same, using C-like syntax.
17
18 LIMIT=10
19
20 for ((a=1; a <= LIMIT; a++)) \# Double parentheses, and "LIMIT" with no "$".
21 do
22 echo -n "$a "
23 done
                               # A construct borrowed from 'ksh93'.
24
25 echo; echo
26
27 # +=========
28
29 # Let's use the C "comma operator" to increment two variables simultaneously.
31 for ((a=1, b=1; a \le LIMIT; a++, b++)) # The comma chains together operations.
33 echo -n "$a-$b "
34 done
36 echo; echo
37
38 exit 0
```

See also Example 26-16, Example 26-17, and Example A-6.

Now, a for loop used in a "real-life" context.

Example 10-13. Using *efax* in batch mode

```
1 #!/bin/bash
 2 # Faxing (must have 'efax' package installed).
4 EXPECTED_ARGS=2
5 E_BADARGS=65
PCMCIA modem card default port.
7 #
8
9 if [ $# -ne $EXPECTED_ARGS ]
10 # Check for proper number of command line args.
12 echo "Usage: `basename $0` phone# text-file"
13 exit $E_BADARGS
14 fi
15
16
17 if [ ! -f "$2" ]
18 then
   echo "File $2 is not a text file."
19
   # File is not a regular file, or does not exist.
21 exit $E_BADARGS
22 fi
```

```
23
24
25 fax make $2
                           # Create fax-formatted files from text files.
27 for file in (1s \ 2.0*) # Concatenate the converted files.
                           # Uses wild card (filename "globbing")
29
                      #+ in variable list.
30 do
31 fil="$fil $file"
32 done
33
34 efax -d "$MODEM_PORT" -t "T$1" $fil # Finally, do the work.
35 # Trying adding -o1 if above line fails.
36
37
38 # As S.C. points out, the for-loop can be eliminated with
39 # efax -d /dev/ttvS2 -o1 -t "T$1" $2.0*
40 #+ but it's not quite as instructive [grin].
41
42 exit $?  # Also, efax sends diagnostic messages to stdout.
```

while

This construct tests for a condition at the top of a loop, and keeps looping as long as that condition is true (returns a 0 exit status). In contrast to a for loop, a *while loop* finds use in situations where the number of loop repetitions is not known beforehand.

```
while [ condition]
do
  command(s)...
done
```

The bracket construct in a *while loop* is nothing more than our old friend, the <u>test brackets</u> used in an *if/then* test. In fact, a *while loop* can legally use the more versatile <u>double brackets construct</u> (while [[condition]]).

As is the case with *for loops*, placing the *do* on the same line as the condition test requires a semicolon.

```
while [ condition]; do
```

Note that the *test brackets* are *not* mandatory in a *while* loop. See, for example, the <u>getopts construct</u>.

Example 10-14. Simple while loop

```
1 #!/bin/bash
3 var0=0
4 LIMIT=10
6 while [ "$var0" -lt "$LIMIT" ]
7 #
8 # Spaces, because these are "test-brackets" . . .
9 do
                         # -n suppresses newline.
10
   echo -n "$var0 "
11
                             Space, to separate printed out numbers.
12
13
   var0=`expr $var0 + 1`
                            # var0=$(($var0+1)) also works.
14
                             \# var0=$((var0 + 1)) also works.
```

```
# let "var0 += 1" also works.

16 done  # Various other methods also work.

17

18 echo
19
20 exit 0
```

Example 10-15. Another while loop

```
1 #!/bin/bash
3 echo
                                 # Equivalent to:
5 while [ "$var1" != "end" ]
                               # while test "$var1" != "end"
 6 do
7
   echo "Input variable #1 (end to exit) "
   read var1
                            # Not 'read $var1' (why?).
 8
   echo "variable #1 = $var1" # Need quotes because of "#" . . .
9
10 # If input is 'end', echoes it here.
11
    # Does not test for termination condition until top of loop.
12
13 done
15 exit 0
```

A *while loop* may have multiple conditions. Only the final condition determines when the loop terminates. This necessitates a slightly different loop syntax, however.

Example 10-16. while loop with multiple conditions

```
1 #!/bin/bash
 3 var1=unset
 4 previous=$var1
 6 while echo "previous-variable = $previous"
 7
       echo
         previous=$var1
 8
        [ "$var1" != end ] # Keeps track of what $var1 was previously.
 9
         # Four conditions on "while", but only last one controls loop.
10
         # The *last* exit status is the one that counts.
11
12 do
13 echo "Input variable #1 (end to exit) "
    read var1
    echo "variable #1 = $var1"
15
16 done
17
18 # Try to figure out how this all works.
19 # It's a wee bit tricky.
2.0
21 exit 0
```

As with a *for loop*, a *while loop* may employ C-style syntax by using the double parentheses construct (see also Example 9-33).

Example 10-17. C-style syntax in a while loop

```
1 #!/bin/bash
 2 # wh-loopc.sh: Count to 10 in a "while" loop.
 4 LIMIT=10
 5 a=1
 7 while [ "$a" -le $LIMIT ]
 8 do
 9 echo -n "$a "
10 let "a+=1"
              # No surprises, so far.
11 done
12
13 echo; echo
14
15 # +==========++
16
17 # Now, repeat with C-like syntax.
18
19 ((a = 1)) # a=1
20 \# Double parentheses permit space when setting a variable, as in C.
22 while (( a <= LIMIT ))  # Double parentheses, and no "$" preceding variables.
23 do
24 echo -n "$a "
25 ((a += 1)) # let "a+=1"
26 # Yes, indeed.
27 # Double parentheses permit incrementing a variable with C-like syntax.
28 done
29
30 echo
31
32 # C programmers can feel right at home in Bash.
33
34 exit 0
```

Inside its test brackets, a while loop can call a function.

```
1 t=0
 3 condition ()
 4 {
 5
    ((t++))
 6
   if [ $t -lt 5 ]
 8 then
     return 0 # true
9
10 else
11 return 1 # false
12 fi
13 }
14
15 while condition
16 # ^^^^^
       Function call -- four loop iterations.
18 do
19 echo "Still going: t = $t"
20 done
21
22 # Still going: t = 1
23 \# Still going: t = 2
24 \# Still going: t = 3
```

```
Similar to the <u>if-test</u> construct, a while loop can omit the test brackets.

1 while condition
2 do
3 ...
4 done
```

By coupling the power of the <u>read</u> command with a *while loop*, we get the handy <u>while read</u> construct, useful for reading and parsing files.

```
1 cat $filename | # Supply input from a file.
2 while read line # As long as there is another line to read ...
3 do
4 ...
5 done
```

A while loop may have its stdin redirected to a file by a < at its end.

A while loop may have its stdin supplied by a pipe.

until

This construct tests for a condition at the top of a loop, and keeps looping as long as that condition is false (opposite of *while loop*).

```
until [ condition-is-true]
do
  command(s)...
done
```

Note that an *until loop* tests for the terminating condition at the top of the loop, differing from a similar construct in some programming languages.

As is the case with *for loops*, placing the *do* on the same line as the condition test requires a semicolon.

```
until [ condition-is-true]; do
```

Example 10-18. until loop

```
1 #!/bin/bash
2
3 END_CONDITION=end
4
5 until [ "$var1" = "$END_CONDITION" ]
6 # Tests condition here, at top of loop.
7 do
8   echo "Input variable #1 "
9   echo "($END_CONDITION to exit)"
10   read var1
11   echo "variable #1 = $var1"
12   echo
13 done
14
15 exit 0
```

How to choose between a *for* loop or a *while* loop or *until* loop? In **C**, you would typically use a *for* loop when the number of loop iterations is known beforehand. With *Bash*, however, the situation is fuzzier. The Bash *for* loop is more loosely structured and more flexible than its equivalent in other languages. Therefore, feel free to use whatever type of loop gets the job done in the simplest way.

Notes

until a given condition is met.

The Double Parentheses Construct Up Nested Loops
Advanced Bash-Scripting Guide: An in-depth exploration of the art of shell scripting
Prev Chapter 10. Loops and Branches Next

10.2. Nested Loops

A *nested loop* is a loop within a loop, an inner loop within the body of an outer one. How this works is that the first pass of the outer loop triggers the inner loop, which executes to completion. Then the second pass of the outer loop triggers the inner loop again. This repeats until the outer loop finishes. Of course, a *break* within either the inner or outer loop would interrupt this process.

Example 10-19. Nested Loop

```
1 #!/bin/bash
2 # nested-loop.sh: Nested "for" loops.
                   # Set outer loop counter.
4 outer=1
6 # Beginning of outer loop.
7 for a in 1 2 3 4 5
8 do
   echo "Pass $outer in outer loop."
   echo "-----
10
            # Reset inner loop counter.
11
   inner=1
12
    13
14
   # Beginning of inner loop.
1.5
   for b in 1 2 3 4 5
16
17
  echo "Pass $inner in inner loop."
18
    let "inner+=1" # Increment inner loop counter.
19
20
   # End of inner loop.
21
    # -----
2.2
   let "outer+=1" # Increment outer loop counter.
23
                   # Space between output blocks in pass of outer loop.
24
25 done
26 # End of outer loop.
27
28 exit 0
```

See <u>Example 26-11</u> for an illustration of nested <u>while loops</u>, and <u>Example 26-13</u> to see a while loop nested inside an <u>until loop</u>.

PrevHomeNextLoops and BranchesUpLoop ControlAdvanced Bash-Scripting Guide: An in-depth exploration of the art of shell scriptingPrevChapter 10. Loops and BranchesNext

10.3. Loop Control

Commands Affecting Loop Behavior

break, continue

The **break** and **continue** loop control commands [1] correspond exactly to their counterparts in other programming languages. The **break** command terminates the loop (breaks out of it), while **continue** causes a jump to the next *iteration* (repetition) of the loop, skipping all the remaining commands in that particular loop cycle.

Example 10-20. Effects of break and continue in a loop

```
1 #!/bin/bash
3 LIMIT=19 # Upper limit
5 echo
 6 echo "Printing Numbers 1 through 20 (but not 3 and 11)."
8 a=0
10 while [ $a -le "$LIMIT" ]
11 do
12 a=$(($a+1))
13
14 if [ "$a" -eq 3 ] || [ "$a" -eq 11 ] # Excludes 3 and 11.
15 then
16
    continue
               # Skip rest of this particular loop iteration.
17 fi
18
19 echo -n "$a " # This will not execute for 3 and 11.
20 done
21
22 # Exercise:
23 # Why does loop print up to 20?
25 echo; echo
26
27 echo Printing Numbers 1 through 20, but something happens after 2.
30
31 # Same loop, but substituting 'break' for 'continue'.
32
33 a=0
34
35 while [ "$a" -le "$LIMIT" ]
36 do
37 a=$(($a+1))
38
39 if [ "$a" -gt 2 ]
40
   then
41
    break # Skip entire rest of loop.
42
43
44 echo -n "$a "
45 done
46
47 echo; echo; echo
48
49 exit 0
```

The **break** command may optionally take a parameter. A plain **break** terminates only the innermost loop in which it is embedded, but a **break N** breaks out of *N* levels of loop.

Example 10-21. Breaking out of multiple loop levels

```
1 #!/bin/bash
 2 # break-levels.sh: Breaking out of loops.
 4 # "break N" breaks out of N level loops.
 6 for outerloop in 1 2 3 4 5
 7 do
 8
    echo -n "Group $outerloop:
 9
10
11 for innerloop in 1 2 3 4 5
12 do
13
     echo -n "$innerloop "
14
     if [ "$innerloop" -eq 3 ]
1.5
16
     then
       break # Try break 2 to see what happens.
17
18
               # ("Breaks" out of both inner and outer loops.)
     fi
19
20
21
22
23
    echo
24 done
25
26 echo
2.7
28 exit 0
```

The **continue** command, similar to **break**, optionally takes a parameter. A plain **continue** cuts short the current iteration within its loop and begins the next. A **continue N** terminates all remaining iterations at its loop level and continues with the next iteration at the loop, N levels above.

Example 10-22. Continuing at a higher loop level

```
1 #!/bin/bash
 2 # The "continue N" command, continuing at the Nth level loop.
 4 for outer in I II III IV V
                                      # outer loop
 5 do
    echo; echo -n "Group $outer: "
 6
 9
    for inner in 1 2 3 4 5 6 7 8 9 10 # inner loop
10
11
     if [ "$inner" -eq 7 ]
12
     then
13
       continue 2 # Continue at loop on 2nd level, that is "outer loop".
14
1.5
                    # Replace above line with a simple "continue"
16
                     # to see normal loop behavior.
      fi
17
18
```

Example 10-23. Using *continue N* in an actual task

```
1 # Albert Reiner gives an example of how to use "continue N":
2 # -----
 3
 4\ \# Suppose I have a large number of jobs that need to be run, with
 5 #+ any data that is to be treated in files of a given name pattern in a
 6 #+ directory. There are several machines that access this directory, and
 7 #+ I want to distribute the work over these different boxen. Then I
 8 #+ usually nohup something like the following on every box:
10 while true
11 do
12 for n in .iso.*
13 do
14 [ "$n" = ".iso.opts" ] && continue
1.5
     beta=${n#.iso.}
16
     [ -r .Iso.$beta ] && continue
17
      [ -r .lock.$beta ] && sleep 10 && continue
18
     lockfile -r0 .lock.$beta || continue
19
     echo -n "$beta: " `date`
     run-isotherm $beta
20
21
     date
     ls -alF .Iso.$beta
2.2.
23
     [ -r .Iso.$beta ] && rm -f .lock.$beta
2.4
     continue 2
25 done
26 break
27 done
28
29 \# The details, in particular the sleep N, are particular to my
30 #+ application, but the general pattern is:
31
32 while true
33 do
34 for job in {pattern}
35 do
     { job already done or running} && continue
37
     {mark job as running, do job, mark job as done}
38
     continue 2
39
   done
40
   break
                # Or something like `sleep 600' to avoid termination.
41 done
42.
43 # This way the script will stop only when there are no more jobs to do
44 #+ (including jobs that were added during runtime). Through the use
45 #+ of appropriate lockfiles it can be run on several machines
46 #+ concurrently without duplication of calculations [which run a couple
47 #+ of hours in my case, so I really want to avoid this]. Also, as search
```

```
48 #+ always starts again from the beginning, one can encode priorities in
49 #+ the file names. Of course, one could also do this without `continue 2',
50 #+ but then one would have to actually check whether or not some job
51 #+ was done (so that we should immediately look for the next job) or not
52 #+ (in which case we terminate or sleep for a long time before checking
53 #+ for a new job).
```

1 The **continue N** construct is difficult to understand and tricky to use in any meaningful context. It is probably best avoided.

Notes

[1] These are shell <u>builtins</u>, whereas other loop commands, such as <u>while</u> and <u>case</u>, are <u>keywords</u>.

Prev Home Nexted Loops

Advanced Bash-Scripting Guide: An in-depth exploration of the art of shell scripting

Prev Chapter 10. Loops and Branches Next

10.4. Testing and Branching

The **case** and **select** constructs are technically not loops, since they do not iterate the execution of a code block. Like loops, however, they direct program flow according to conditions at the top or bottom of the block.

Controlling program flow in a code block

case (in) / esac

The **case** construct is the shell scripting analog to **switch** in C/C++. It permits branching to one of a number of code blocks, depending on condition tests. It serves as a kind of shorthand for multiple if/then/else statements and is an appropriate tool for creating menus.

```
case "$variable" in

"$condition1")
command...
;;

"$condition2")
command...
;;
esac
```

- ♦ Quoting the variables is not mandatory, since word splitting does not take place.
- ♦ Each test line ends with a right paren).
- ♦ Each condition block ends with a *double* semicolon ;;.
- ♦ The entire **case** block terminates with an **esac** (*case* spelled backwards).

Example 10-24. Using case

```
1 #!/bin/bash
 2 # Testing ranges of characters.
 4 echo; echo "Hit a key, then hit return."
 5 read Keypress
 7 case "$Keypress" in
    [[:lower:]] ) echo "Lowercase letter";;
    [[:upper:]] ) echo "Uppercase letter";;
10 [0-9] ) echo "Digit";;
11 *
                  ) echo "Punctuation, whitespace, or other";;
11 * ) echo "Punctuation, whitespace, or other";;
12 esac # Allows ranges of characters in [square brackets],
            #+ or POSIX ranges in [[double square brackets.
1.3
14
15 # In the first version of this example,
16 #+ the tests for lowercase and uppercase characters were
17 #+ [a-z] and [A-Z].
18 # This no longer works in certain locales and/or Linux distros.
19 # POSIX is more portable.
20 # Thanks to Frank Wang for pointing this out.
21
22 # Exercise:
```

```
23 # ------
24 # As the script stands, it accepts a single keystroke, then terminates.
25 # Change the script so it accepts repeated input,
26 #+ reports on each keystroke, and terminates only when "X" is hit.
27 # Hint: enclose everything in a "while" loop.
28
29 exit 0
```

Example 10-25. Creating menus using case

```
1 #!/bin/bash
3 # Crude address database
5 clear # Clear the screen.
7 echo "
                 Contact List"
8 echo " Contact List"
9 echo "Choose one of the following persons:"
10 echo
11 echo "[E]vans, Roland"
12 echo "[J]ones, Mildred"
13 echo "[S]mith, Julie"
14 echo "[Z]ane, Morris"
15 echo
16
17 read person
18
19 case "$person" in
20 # Note variable is quoted.
21
22 "E" | "e" )
23 # Accept upper or lowercase input.
24 echo
25 echo "Roland Evans"
26 echo "4321 Floppy Dr."
   echo "Hardscrabble, CO 80753"
27
28 echo "(303) 734-9874"
29 echo "(303) 734-9892 fax"
30 echo "revans@zzy.net"
    echo "Business partner & old friend"
31
32
33 \# Note double semicolon to terminate each option.
34
35
    "J" | "j" )
36
    echo
37
    echo "Mildred Jones"
38
    echo "249 E. 7th St., Apt. 19"
39
    echo "New York, NY 10009"
   echo "(212) 533-2814"
40
41
   echo "(212) 533-9972 fax"
42 echo "milliej@loisaida.com"
43 echo "Ex-girlfriend"
44
   echo "Birthday: Feb. 11"
45
46
47 # Add info for Smith & Zane later.
48
            * )
49
50 # Default option.
51
    # Empty input (hitting RETURN) fits here, too.
52
     echo
```

```
echo "Not yet in database."

;;

secho seac

;

secho secho

secho secho

secho secho

secho secho secho secho secho secho secho secho secho secho secho secho secho secho secho secho secho secho secho secho secho secho secho secho secho secho secho secho secho secho secho secho secho secho secho secho secho secho secho secho secho secho secho secho secho secho secho secho secho secho secho secho secho secho secho secho secho secho secho secho secho secho secho secho secho secho secho secho secho secho secho secho secho secho secho secho secho secho secho secho secho secho secho secho secho secho secho secho secho secho secho secho secho secho secho secho secho secho secho secho secho secho secho secho secho secho secho secho secho secho secho secho secho secho secho secho secho secho secho secho secho secho secho secho secho secho secho secho secho secho secho secho secho secho secho secho secho secho secho secho secho secho secho secho secho secho secho secho secho secho secho secho secho secho secho secho secho secho secho secho secho secho secho secho secho secho secho secho secho secho secho secho secho secho secho secho secho secho secho secho secho secho secho secho secho secho secho secho secho secho secho secho secho secho secho secho secho secho secho secho secho secho secho secho secho secho secho secho secho secho secho secho secho secho secho secho secho secho secho secho secho secho secho secho secho secho secho secho secho secho secho secho secho secho secho secho secho secho secho secho secho secho secho secho secho secho secho secho secho secho secho secho secho secho secho secho secho secho secho secho secho secho secho secho secho secho secho secho secho secho secho secho secho secho secho secho secho secho secho secho secho secho secho secho secho secho secho secho secho secho secho secho secho secho secho secho secho secho secho secho secho secho secho secho secho secho secho secho secho secho secho secho secho secho secho secho secho secho secho secho secho secho secho secho secho secho sec
```

An exceptionally clever use of **case** involves testing for command-line parameters.

```
1 #! /bin/bash
 3 case "$1" in
 4 "") echo "Usage: ${0##*/} <filename>"; exit $E_PARAM;;
                        # No command-line parameters,
                        # or first parameter empty.
 7 # Note that \{0##*/\} is \{var##pattern\} param substitution.
 8
                        # Net result is $0.
 9
10 -*) FILENAME=./$1;; # If filename passed as argument ($1)
                         #+ starts with a dash,
11
12
                         #+ replace it with ./$1
13
                         #+ so further commands don't interpret it
14
                         #+ as an option.
15
16 * ) FILENAME=$1;; # Otherwise, $1.
17 esac
```

Here is an more straightforward example of command-line parameter handling:

```
1 #! /bin/bash
2
 3
4 while [$\# -gt 0]; do \# Until you run out of parameters . . .
 5 case "$1" in
 6
     -d|--debug)
                # "-d" or "--debug" parameter?
 7
 8
               DEBUG=1
9
10 \quad -c|--conf|
               CONFFILE="$2"
11
12
               shift
13
               if [ ! -f $CONFFILE ]; then
                echo "Error: Supplied file doesn't exist!"
14
                 exit $E_CONFFILE # File not found error.
15
               fi
16
17
               ;;
18
   esac
19
   shift
          # Check next set of parameters.
20 done
21
22 # From Stefano Falsetto's "Log2Rot" script,
23 #+ part of his "rottlog" package.
24 # Used with permission.
```

A case construct can filter strings for globbing patterns.

Example 10-27. Simple string matching

```
1 #!/bin/bash
 2 # match-string.sh: simple string matching
  4 match_string ()
  5 {
  6
    MATCH=0
     NOMATCH=90
     PARAMS=2
  8
                 # Function requires 2 arguments.
  9
    BAD_PARAMS=91
 10
11
    [ $# -eq $PARAMS ] || return $BAD_PARAMS
12
13 case "$1" in
14 "$2") return $MATCH;;
15 * ) return $NOMATCH;;
16
    esac
17
18 }
19
20
21 a=one
22 b=two
23 c=three
24 d=two
25
27 match_string $a  # wrong number of parameters
28 echo $?
                       # 91
 30 match_string $a $b # no match
31 echo $?
32
33 match_string $b $d # match
34 echo $?
35
36
37 exit 0
```

Example 10-28. Checking for alphabetic input

```
1 #!/bin/bash
 2 # isalpha.sh: Using a "case" structure to filter a string.
4 SUCCESS=0
5 FAILURE=-1
7 isalpha () # Tests whether *first character* of input string is alphabetic.
9 if [ -z "$1" ]
                             # No argument passed?
10 then
11 return $FAILURE
12 fi
13
14 case "$1" in
15 [a-zA-Z]*) return $SUCCESS;; # Begins with a letter?
   17 esac
               # Compare this with "isalpha ()" function in C.
18 }
19
20
21 isalpha2 () # Tests whether *entire string* is alphabetic.
22 {
23 [ $# -eq 1 ] || return $FAILURE
24
25 case $1 in
26 *[!a-zA-Z]*|"") return $FAILURE;;
27
               *) return $SUCCESS;;
28 esac
29 }
30
31 isdigit () # Tests whether *entire string* is numerical.
              # In other words, tests for integer variable.
33 [ $# -eq 1 ] || return $FAILURE
34
35 case $1 in
    *[!0-9]*|"") return $FAILURE;;
36
        *) return $SUCCESS;;
37
38 esac
39 }
40
41
42
43 check_var () # Front-end to isalpha ().
44 {
45 if isalpha "$@"
46 then
47 echo "\"$*\" begins with an alpha character."
48 if isalpha2 "$@"
49 then # No point in testing if first char is non-alpha.
50 echo "\"$*\" contains only alpha characters."
51 else
echo "\"$*\" contains at least one non-alpha character."
53 fi
54 else

101 # Exercise:
102 # -----
103 # Write an 'isfloat ()' function that tests for floating point numbers.
104 # Hint: The function duplicates 'isdigit ()',
105 #+ but adds a test for a mandatory decimal point.
```

select

The **select** construct, adopted from the Korn Shell, is yet another tool for building menus.

```
select variable[in list]
do
  command...
break
done
```

This prompts the user to enter one of the choices presented in the variable list. Note that **select** uses the PS3 prompt (#?) by default, but that this may be changed.

Example 10-29. Creating menus using select

```
1 #!/bin/bash
2
3 PS3='Choose your favorite vegetable: ' # Sets the prompt string.
4
5 echo
6
7 select vegetable in "beans" "carrots" "potatoes" "onions" "rutabagas"
```

```
8 do
9 echo
10 echo "Your favorite veggie is $vegetable."
11 echo "Yuck!"
12 echo
13 break # What happens if there is no 'break' here?
14 done
15
16 exit 0
```

If in *list* is omitted, then **select** uses the list of command line arguments (\$@) passed to the script or to the function in which the **select** construct is embedded.

Compare this to the behavior of a

for variable [in list]

construct with the in list omitted.

Example 10-30. Creating menus using *select* in a function

```
1 #!/bin/bash
3 PS3='Choose your favorite vegetable: '
4
5 echo
6
7 choice_of()
9 select vegetable
10 # [in list] omitted, so 'select' uses arguments passed to function.
11 do
12 echo
13 echo "Your favorite veggie is $vegetable."
14 echo "Yuck!"
15 echo
16 break
17 done
18 }
19
20 choice_of beans rice carrots radishes tomatoes spinach
21 # $1 $2 $3 $4 $5
                                         $6
22 #
          passed to choice_of() function
23
24 exit 0
```

See also Example 34-3.

Advanced Bash-Scripting Guide: An in-depth exploration of the art of shell scripting

<u>Prev</u> <u>Next</u>

Chapter 11. Command Substitution

Command substitution reassigns the output of a command [1] or even multiple commands; it literally plugs the command output into another context. [2]

The classic form of command substitution uses *backquotes* (`...`). Commands within backquotes (backticks) generate command line text.

```
1 script_name=`basename $0`
2 echo "The name of this script is $script_name."
```

The output of commands can be used as arguments to another command, to set a variable, and even for generating the argument list in a <u>for</u> loop.

```
1 rm `cat filename` # "filename" contains a list of files to delete.
 3 # S. C. points out that "arg list too long" error might result.
 4 # Better is xargs rm -- < filename
 5 \# ( -- covers those cases where "filename" begins with a "-" )
 7 textfile_listing=`ls *.txt`
 8 # Variable contains names of all *.txt files in current working directory.
9 echo $textfile_listing
10
11 textfile_listing2=$(ls *.txt)  # The alternative form of command substitution.
12 echo $textfile_listing2
13 # Same result.
14
15 # A possible problem with putting a list of files into a single string
16 # is that a newline may creep in.
17 #
18 # A safer way to assign a list of files to a parameter is with an array.
19 # shopt -s nullglob # If no match, filename expands to nothing.
        textfile_listing=( *.txt )
21 #
22 # Thanks, S.C.
```

Command substitution invokes a subshell.

1 Command substitution may result in word splitting.

```
1 COMMAND 'echo a b' # 2 args: a and b
2
3 COMMAND "'echo a b'" # 1 arg: "a b"
4
5 COMMAND 'echo' # no arg
6
7 COMMAND "'echo'" # one empty arg
8
9
10 # Thanks, S.C.
```

Even when there is no word splitting, command substitution can remove trailing newlines.

```
1 # cd "`pwd`" # This should always work.
2 # However...
3
4 mkdir 'dir with trailing newline
5 '
6
7 cd 'dir with trailing newline
8 '
9
```

```
10 cd "`pwd`" # Error message:
11 # bash: cd: /tmp/file with trailing newline: No such file or directory
12
13 cd "$PWD" # Works fine.
1 4
15
16
17
18
19 old_tty_setting=$(stty -g) # Save old terminal setting.
20 echo "Hit a key "
21 stty -icanon -echo
                               # Disable "canonical" mode for terminal.
22
                                # Also, disable *local* echo.
23 key=(dd bs=1 count=1 2 > /dev/null) # Using 'dd' to get a keypress.
24 stty "$old_tty_setting" # Restore old setting.
25 echo "You hit ${#key} key." # ${#variable} = number of characters in $variable
26 #
27 # Hit any key except RETURN, and the output is "You hit 1 key."
28 # Hit RETURN, and it's "You hit 0 key."
29 # The newline gets eaten in the command substitution.
30
31 Thanks, S.C.
```

Using **echo** to output an *unquoted* variable set with command substitution removes trailing newlines characters from the output of the reassigned command(s). This can cause unpleasant surprises.

Command substitution even permits setting a variable to the contents of a file, using either <u>redirection</u> or the cat command.

```
11 if [ -e "/proc/ide/${disk[$device]}/media" ] ; then
12
              hdmedia=`cat /proc/ide/${disk[$device]}/media`
13 ...
14 fi
15 #
16 #
17 if [ ! -n "`uname -r | grep -- "-"`" ]; then
         ktag="`cat /proc/version`"
19 ...
2.0 fi
21 #
22 #
23 if [ $usb = "1" ]; then
       sleep 5
       mouseoutput=`cat /proc/bus/usb/devices 2>/dev/null|grep -E "^I.*Cls=03.*Prot=02"`
       kbdoutput=`cat /proc/bus/usb/devices 2>/dev/null|grep -E "^I.*Cls=03.*Prot=01"`
27 ...
28 fi
```

① Do not set a variable to the contents of a *long* text file unless you have a very good reason for doing so. Do not set a variable to the contents of a *binary* file, even as a joke.

Example 11-1. Stupid script tricks

```
1 #!/bin/bash
 2 # stupid-script-tricks.sh: Don't try this at home, folks.
3 # From "Stupid Script Tricks," Volume I.
 5
 6 dangerous_variable=`cat /boot/vmlinuz` # The compressed Linux kernel itself.
8 echo "string-length of \$dangerous_variable = ${#dangerous_variable}"
9 # string-length of $dangerous_variable = 794151
10 # (Does not give same count as 'wc -c /boot/vmlinuz'.)
11
12 # echo "$dangerous_variable"
13 # Don't try this! It would hang the script.
14
15
16 # The document author is aware of no useful applications for
17 #+ setting a variable to the contents of a binary file.
18
19 exit 0
```

Notice that a *buffer overrun* does not occur. This is one instance where an interpreted language, such as Bash, provides more protection from programmer mistakes than a compiled language.

Command substitution permits setting a variable to the output of a <u>loop</u>. The key to this is grabbing the output of an <u>echo</u> command within the loop.

Example 11-2. Generating a variable from a loop

```
1 #!/bin/bash
2 # csubloop.sh: Setting a variable to the output of a loop.
3
4 variable1=`for i in 1 2 3 4 5
5 do
6 echo -n "$i" # The 'echo' command is critical
7 done` #+ to command substitution here.
8
```

```
9 echo "variable1 = $variable1" # variable1 = 12345
10
11
12 i=0
13 variable2=`while [ "$i" -lt 10 ]
15 echo -n "$i"
                                # Again, the necessary 'echo'.
16 let "i += 1"
                                 # Increment.
17 done`
18
19 echo "variable2 = $variable2" # variable2 = 0123456789
20
21 # Demonstrates that it's possible to embed a loop
22 #+ within a variable declaration.
23
24 exit 0
```

Command substitution makes it possible to extend the toolset available to Bash. It is simply a matter of writing a program or script that outputs to stdout (like a well-behaved UNIX tool should) and assigning that output to a variable.

```
1 #include <stdio.h>
2
3 /* "Hello, world." C program */
4
5 int main()
6 {
7    printf( "Hello, world." );
8    return (0);
9 }
bash$ gcc -o hello hello.c

1 #!/bin/bash
2 # hello.sh
3
4 greeting=`./hello`
5 echo $greeting
bash$ sh hello.sh
Hello, world.
```

The \$(...) form has superseded backticks for command substitution.

```
1 output=$(sed -n /"$1"/p $file) # From "grp.sh" example.
2
3 # Setting a variable to the contents of a text file.
4 File_contents1=$(cat $file1)
5 File_contents2=$(<$file2) # Bash permits this also.</pre>
```

The \$(...) form of command substitution treats a double backslash in a different way than `...`.

```
bash$ echo `echo \\`
bash$ echo $(echo \\)
\
```

The \$(...) form of command substitution permits nesting. [3]

```
1 word_count=$( wc -w $(ls -l | awk '{print $9}') )
```

Or, for something a bit more elaborate . . .

Example 11-3. Finding anagrams

```
1 #!/bin/bash
 2 # agram2.sh
 3 # Example of nested command substitution.
 5 # Uses "anagram" utility
 6 #+ that is part of the author's "yawl" word list package.
7 # http://ibiblio.org/pub/Linux/libs/yawl-0.3.2.tar.gz
8 # http://personal.riverusers.com/~thegrendel/yawl-0.3.2.tar.gz
10 E_NOARGS=66
11 E_BADARG=67
12 MINLEN=7
13
14 if [ -z "$1" ]
15 then
16 echo "Usage $0 LETTERSET"
17 exit $E_NOARGS # Script needs a command-line argument.
18 elif [ ${#1} -lt $MINLEN ]
19 then
20 echo "Argument must have at least $MINLEN letters."
21 exit $E_BADARG
22 fi
23
24
25
26 FILTER='....'
                          # Must have at least 7 letters.
27 # 1234567
28 Anagrams=( $(echo $(anagram $1 | grep $FILTER) ) )
29 # $( s( nested command sub. ))
30 #
                        array assignment
31
32 echo
33 echo "${#Anagrams[*]} 7+ letter anagrams found"
34 echo
35 echo ${Anagrams[0]}
                          # First anagram.
36 echo ${Anagrams[1]}
                          # Second anagram.
                          # Etc.
37
38
39 # echo "${Anagrams[*]}" # To list all the anagrams in a single line . . .
41 # Look ahead to the "Arrays" chapter for enlightenment on
42 #+ what's going on here.
44 # See also the agram.sh script for an example of anagram finding.
45
46 exit $?
```

- 14. Example 15-45
- 15. Example 15-46
- 16. Example 15-47

Notes

- [1] For purposes of *command substitution*, a **command** may be an external system command, an internal scripting <u>builtin</u>, or even <u>a script function</u>.
- [2] In a more technically correct sense, *command substitution* extracts the stdout of a command, then assigns it to a variable using the = operator.
- [3] In fact, nesting with backticks is also possible, but only by escaping the inner backticks, as John Default points out.

1 word_count=` wc -w \`ls -l | awk '{print \$9}'\` `

PrevHomeNextTesting and BranchingUpArithmetic Expansion

Advanced Bash-Scripting Guide: An in-depth exploration of the art of shell scripting

<u>Prev</u> <u>Next</u>

Chapter 12. Arithmetic Expansion

Arithmetic expansion provides a powerful tool for performing (integer) arithmetic operations in scripts. Translating a string into a numerical expression is relatively straightforward using *backticks*, *double parentheses*, or *let*.

Variations

Arithmetic expansion with <u>backticks</u> (often used in conjunction with <u>expr</u>)

```
1 z=`expr $z + 3` # The 'expr' command performs the expansion.
```

Arithmetic expansion with double parentheses, and using let

The use of *backticks* (*backquotes*) in arithmetic expansion has been superseded by *double parentheses* -- ((...)) and \$((...)) -- and also by the very convenient let construction.

```
1 z = \$ ((\$z+3))
 2 z=\$((z+3))
                                                # Also correct.
                                                # Within double parentheses,
 4
                                               #+ parameter dereferencing
                                               #+ is optional.
 6
7 # $((EXPRESSION)) is arithmetic expansion. # Not to be confused with
                                               #+ command substitution.
9
10
11
12 # You may also use operations within double parentheses without assignment.
13
   n=0
14
15
   echo "n = $n"
                                                \# n = 0
16
17 ((n += 1))
                                                # Increment.
18 # (( $n += 1 )) is incorrect!
    echo "n = $n"
                                                \# n = 1
19
2.0
21
22 let z=z+3
23 let "z += 3" # Quotes permit the use of spaces in variable assignment.
                 # The 'let' operator actually performs arithmetic evaluation,
25
                 #+ rather than expansion.
```

Examples of arithmetic expansion in scripts:

- 1. Example 15-9
- 2. Example 10-14
- 3. Example 26-1
- 4. Example 26-11
- 5. <u>Example A-17</u>

Chapter 13. Recess Time

This bizarre little intermission gives the reader a chance to relax and maybe laugh a bit.

Fellow Linux user, greetings! You are reading something which will bring you luck and good fortune. Just e-mail a copy of this document to 10 of your friends. Before making the copies, send a 100-line Bash script to the first person on the list at the bottom of this letter. Then delete their name and add yours to the bottom of the list.

Don't break the chain! Make the copies within 48 hours. Wilfred P. of Brooklyn failed to send out his ten copies and woke the next morning to find his job description changed to "COBOL programmer." Howard L. of Newport News sent out his ten copies and within a month had enough hardware to build a 100-node Beowulf cluster dedicated to playing *Tuxracer*. Amelia V. of Chicago laughed at this letter and broke the chain. Shortly thereafter, a fire broke out in her terminal and she now spends her days writing documentation for MS Windows.

Don't break the chain! Send out your ten copies today!

Chapter 14. Internal Commands and Builtins

A *builtin* is a **command** contained within the Bash tool set, literally *built in*. This is either for performance reasons -- builtins execute faster than external commands, which usually require *forking off* a separate process -- or because a particular builtin needs direct access to the shell internals.

When a command or the shell itself initiates (or *spawns*) a new subprocess to carry out a task, this is called *forking*. This new process is the *child*, and the process that *forked* it off is the *parent*. While the *child process* is doing its work, the *parent process* is still executing.

Note that while a *parent process* gets the *process ID* of the *child process*, and can thus pass arguments to it, *the reverse is not true*. This can create problems that are subtle and hard to track down.

Example 14-1. A script that forks off multiple instances of itself

```
1 #!/bin/bash
 2 # spawn.sh
 3
 5 PIDS=$(pidof sh $0) # Process IDs of the various instances of this script.
6 P_array=( $PIDS )  # Put them in an array (why?).
7 echo $PIDS  # Show process IDs of parent and child processes.
8 let "instances = ${#P_array[*]} - 1" # Count elements, less 1.
                                   # Why subtract 1?
10 echo "$instances instance(s) of this script running."
11 echo "[Hit Ctl-C to exit.]"; echo
13
16
17 exit 0 # Not necessary; script will never get to here.
18
                      # Why not?
19
20 # After exiting with a Ctl-C,
21 #+ do all the spawned instances of the script die?
22 # If so, why?
23
24 # Note:
25 # ---
26 # Be careful not to run this script too long.
27 # It will eventually eat up too many system resources.
29 # Is having a script spawn multiple instances of itself
30 #+ an advisable scripting technique.
31 # Why or why not?
```

Generally, a Bash *builtin* does not fork a subprocess when it executes within a script. An external system command or filter in a script usually *will* fork a subprocess.

A builtin may be a synonym to a system command of the same name, but Bash reimplements it internally. For example, the Bash **echo** command is not the same as /bin/echo, although their behavior is almost identical.

```
1 #!/bin/bash
2
3 echo "This line uses the \"echo\" builtin."
4 /bin/echo "This line uses the /bin/echo system command."
```

A *keyword* is a *reserved* word, token or operator. Keywords have a special meaning to the shell, and indeed are the building blocks of the shell's syntax. As examples, "for", "while", "do", and "!" are keywords. Similar to a <u>builtin</u>, a keyword is hard-coded into Bash, but unlike a *builtin*, a keyword is not in itself a command, but a *subunit of a larger command structure*. [1]

I/O

echo

prints (to stdout) an expression or variable (see Example 4-1).

```
1 echo Hello
2 echo $a
```

An **echo** requires the −e option to print escaped characters. See <u>Example 5-2</u>.

Normally, each **echo** command prints a terminal newline, but the -n option suppresses this.

An echo can be used to feed a sequence of commands down a pipe.

```
1 if echo "$VAR" | grep -q txt # if [[ $VAR = *txt* ]]
2 then
3 echo "$VAR contains the substring sequence \"txt\""
4 fi
```

An **echo**, in combination with <u>command substitution</u> can set a variable.

```
a='echo "HELLO" | tr A-Z a-z'
```

See also Example 15-21, Example 15-3, Example 15-45, and Example 15-46. Be aware that **echo** 'command' deletes any linefeeds that the output of *command* generates.

The <u>\$IFS</u> (internal field separator) variable normally contains \n (linefeed) as one of its set of <u>whitespace</u> characters. Bash therefore splits the output of *command* at linefeeds into arguments to **echo**. Then **echo** outputs these arguments, separated by spaces.

```
bash$ ls -l /usr/share/apps/kjezz/sounds
-rw-r--r-- 1 root root 1407 Nov 7 2000 reflect.au
-rw-r--r-- 1 root root 362 Nov 7 2000 seconds.au

bash$ echo `ls -l /usr/share/apps/kjezz/sounds`
total 40 -rw-r--r-- 1 root root 716 Nov 7 2000 reflect.au -rw-r--r-- 1 root root ...
```

So, how can we embed a linefeed within an <u>echoed</u> character string?

```
1 # Embedding a linefeed?
2 echo "Why doesn't this string \n split on two lines?"
3 # Doesn't split.
4
5 # Let's try something else.
6
7 echo
```

```
9 echo $"A line of text containing
10 a linefeed."
11 # Prints as two distinct lines (embedded linefeed).
12 # But, is the "$" variable prefix really necessary?
14 echo
15
16 echo "This string splits
17 on two lines."
18 # No, the "$" is not needed.
19
20 echo
21 echo "----"
22 echo
23
24 echo -n $"Another line of text containing
25 a linefeed."
26 # Prints as two distinct lines (embedded linefeed).
27 # Even the -n option fails to suppress the linefeed here.
2.8
29 echo
30 echo
31 echo "----"
32 echo
33 echo
34
35 # However, the following doesn't work as expected.
36 # Why not? Hint: Assignment to a variable.
37 string1=$"Yet another line of text containing
38 a linefeed (maybe)."
39
40 echo $string1
41 # Yet another line of text containing a linefeed (maybe).
43 # Linefeed becomes a space.
45 # Thanks, Steve Parker, for pointing this out.
```

This command is a shell builtin, and not the same as /bin/echo, although its behavior is similar.

```
bash$ type -a echo
 echo is a shell builtin
 echo is /bin/echo
```

printf

The **printf**, formatted print, command is an enhanced **echo**. It is a limited variant of the C language printf() library function, and its syntax is somewhat different.

```
printf format-string... parameter...
```

This is the Bash builtin version of the /bin/printf or /usr/bin/printf command. See the **printf** manpage (of the system command) for in-depth coverage.

1 Older versions of Bash may not support **printf**.

Example 14-2. printf in action

```
1 #!/bin/bash
 2 # printf demo
4 PI=3.14159265358979
5 DecimalConstant=31373
 6 Messagel="Greetings,"
7 Message2="Earthling."
9 echo
10
11 printf "Pi to 2 decimal places = %1.2f" $PI
13 printf "Pi to 9 decimal places = %1.9f" $PI # It even rounds off correctly.
15 printf "\n"
                                               # Prints a line feed,
                                               # Equivalent to 'echo' . . .
16
17
18 printf "Constant = \t%d\n" $DecimalConstant # Inserts tab (\t).
19
20 printf "%s %s \n" $Message1 $Message2
21
22 echo
23
24 # ========#
25 # Simulation of C function, sprintf().
26 # Loading a variable with a formatted string.
28 echo
29
30 Pi12=$(printf "%1.12f" $PI)
31 echo "Pi to 12 decimal places = $Pi12" # Roundoff error!
33 Msg=`printf "%s %s \n" $Message1 $Message2`
34 echo $Msg; echo $Msg
35
36 # As it happens, the 'sprintf' function can now be accessed
37 #+ as a loadable module to Bash,
38 #+ but this is not portable.
40 exit 0
```

Formatting error messages is a useful application of printf

```
1 E_BADDIR=65
  3 var=nonexistent_directory
  4
  5 error()
  6 {
  7
     printf "$@" >&2
     # Formats positional params passed, and sends them to stderr.
  9
     echo
 10
     exit $E_BADDIR
 11 }
 12
 13 cd $var || error $"Can't cd to %s." "$var"
15 # Thanks, S.C.
```

read

"Reads" the value of a variable from stdin, that is, interactively fetches input from the keyboard. The -a option lets **read** get array variables (see Example 26-6).

Example 14-3. Variable assignment, using read

```
1 #!/bin/bash
 2 # "Reading" variables.
 4 echo -n "Enter the value of variable 'var1': "
 5 # The -n option to echo suppresses newline.
 7 read var1
 8 # Note no '$' in front of var1, since it is being set.
10 echo "var1 = $var1"
11
12
13 echo
14
15 # A single 'read' statement can set multiple variables.
16 echo -n "Enter the values of variables 'var2' and 'var3' "
17 echo =n "(separated by a space or tab): "
18 read var2 var3
19 echo "var2 = $var2 var3 = $var3"
20 # If you input only one value,
21 #+ the other variable(s) will remain unset (null).
2.2.
23 exit 0
```

A **read** without an associated variable assigns its input to the dedicated variable <u>\$REPLY</u>.

Example 14-4. What happens when read has no variable

```
1 #!/bin/bash
2 # read-novar.sh
3
4 echo
 6 # ----- #
 7 echo -n "Enter a value: "
8 read var
9 echo "\"var\" = "$var""
10 # Everything as expected here.
11 # ----- #
12
13 echo
14
15 # -----
16 echo -n "Enter another value: "
17 read # No variable supplied for 'read', therefore...
18
               #+ Input to 'read' assigned to default variable, $REPLY.
19 var="$REPLY"
20 echo "\"var\" = "$var""
21 # This is equivalent to the first code block.
22 # ---
23
24 echo
25 echo "=========="
26 echo
27
2.8
29 # This example is similar to the "reply.sh" script.
30 # However, this one shows that $REPLY is available
31 #+ even after a 'read' to a variable in the conventional way.
32
33
```

Normally, inputting a \setminus suppresses a newline during input to a **read**. The -r option causes an inputted \setminus to be interpreted literally.

Example 14-5. Multi-line input to read

```
1 #!/bin/bash
 3 echo
 5 echo "Enter a string terminated by a \\, then press <ENTER>."
 6 echo "Then, enter a second string (no \\ this time), and again press <ENTER>."
 8 read var1  # The "\" suppresses the newline, when reading $var1.
9
                # first line \
10
                 #
                      second line
11
12 echo "var1 = $var1"
13 # var1 = first line second line
15 # For each line terminated by a "\"
16 #+ you get a prompt on the next line to continue feeding characters into var1.
17
18 echo; echo
19
20 echo "Enter another string terminated by a \ \ \ , then press <ENTER>."
21 read -r var2 # The -r option causes the "\" to be read literally.
                      first line \
23
24 echo "var2 = $var2"
25 # var2 = first line \
27 # Data entry terminates with the first <ENTER>.
28
29 echo
30
31 exit 0
```

The **read** command has some interesting options that permit echoing a prompt and even reading keystrokes without hitting **ENTER**.

```
1 # Read a keypress without hitting ENTER.
2
3 read -s -n1 -p "Hit a key " keypress
```

```
4 echo; echo "Keypress was "\"$keypress\""."
5
6 # -s option means do not echo input.
7 # -n N option means accept only N characters of input.
8 # -p option means echo the following prompt before reading input.
9
10 # Using these options is tricky, since they need to be in the correct order.
```

The -n option to **read** also allows detection of the **arrow keys** and certain of the other unusual keys.

Example 14-6. Detecting the arrow keys

```
1 #!/bin/bash
 2 # arrow-detect.sh: Detects the arrow keys, and a few more.
 3 # Thank you, Sandro Magi, for showing me how.
 5 # -----
 6 # Character codes generated by the keypresses.
 7 arrowup='\[A'
8 arrowdown='\[B'
9 arrowrt='\[C'
10 arrowleft='\[D'
11 insert='\[2'
12 delete='\[3'
13 # --
14
15 SUCCESS=0
16 OTHER=65
17
18 echo -n "Press a key... "
19 # May need to also press ENTER if a key not listed above pressed.
20 read -n3 key
                     # Read 3 characters.
22 echo -n "$key" | grep "$arrowup" #Check if character code detected.
23 if [ "$?" -eq $SUCCESS ]
24 then
25 echo "Up-arrow key pressed."
26 exit $SUCCESS
27 fi
28
29 echo -n "$key" | grep "$arrowdown"
30 if [ "$?" -eq $SUCCESS ]
31 then
32
   echo "Down-arrow key pressed."
33
    exit $SUCCESS
34 fi
35
36 echo -n "$key" | grep "$arrowrt"
37 if [ "$?" -eq $SUCCESS ]
38 then
39 echo "Right-arrow key pressed."
40 exit $SUCCESS
41 fi
42
43 echo -n "$key" | grep "$arrowleft"
44 if [ "$?" -eq $SUCCESS ]
45 then
46 echo "Left-arrow key pressed."
47 exit $SUCCESS
48 fi
49
50 echo -n "$key" | grep "$insert"
51 if [ "$?" -eq $SUCCESS ]
```

```
52 then
 53 echo "\"Insert\" key pressed."
54 exit $SUCCESS
55 fi
 57 echo -n "$key" | grep "$delete"
 58 if [ "$?" -eq $SUCCESS ]
 59 then
 60 echo "\"Delete\" key pressed."
 61 exit $SUCCESS
 62 fi
 63
 64
 65 echo " Some other key pressed."
 67 exit $OTHER
 68
 69 # ======== #
 70
 71 # Mark Alexander came up with a simplified
 72 #+ version of the above script (Thank you!).
 73 # It eliminates the need for grep.
 74
75 #!/bin/bash
76
77 uparrow=$'\x1b[A'
 78 downarrow=$'\x1b[B'
79 leftarrow=$'\x1b[D'
 80 rightarrow=$'\x1b[C'
 81
 82
    read -s -n3 -p "Hit an arrow key: " x
83
 84
    case "$x" in
 85 $uparrow)
     echo "You pressed up-arrow"
 86
 87
       ;;
    $downarrow)
 88
     echo "You pressed down-arrow"
 89
 90
    $leftarrow)
 91
     echo "You pressed left-arrow"
 92
 93
       ;;
 94
    $rightarrow)
 9.5
      echo "You pressed right-arrow"
     ;;
 96
 97
    esac
98
99 # ======== #
100
101 # Exercise:
102 # --
103 # 1) Add detection of the "Home," "End," "PgUp," and "PgDn" keys.
```

The -n option to read will not detect the ENTER (newline) key.

The -t option to **read** permits timed input (see Example 9-4).

The **read** command may also "read" its variable value from a file <u>redirected</u> to stdin. If the file contains more than one line, only the first line is assigned to the variable. If **read** has more than one parameter, then each of these variables gets assigned a successive <u>whitespace-delineated</u> string. Caution!

Example 14-7. Using read with file redirection

```
1 #!/bin/bash
 3 read var1 <data-file
 4 echo "var1 = $var1"
 5 # var1 set to the entire first line of the input file "data-file"
 7 read var2 var3 <data-file
 8 echo "var2 = $var2 var3 = $var3"
 9 # Note non-intuitive behavior of "read" here.
10 # 1) Rewinds back to the beginning of input file.
11 # 2) Each variable is now set to a corresponding string,
12 # separated by whitespace, rather than to an entire line of text.
13 # 3) The final variable gets the remainder of the line.
14 \ \# \ 4) If there are more variables to be set than whitespace-terminated strings
15 # on the first line of the file, then the excess variables remain empty.
16
17 echo "-----
18
19 # How to resolve the above problem with a loop:
20 while read line
21 do
22
   echo "$line"
23 done <data-file
24 # Thanks, Heiner Steven for pointing this out.
2.5
26 echo "-----"
28 # Use $IFS (Internal Field Separator variable) to split a line of input to
29 # "read", if you do not want the default to be whitespace.
31 echo "List of all users:"
32 OIFS=$IFS; IFS=: # /etc/passwd uses ":" for field separator.
33 while read name passwd uid gid fullname ignore
34 do
35 echo "$name ($fullname)"
36 done </etc/passwd # I/O redirection.
37 IFS=$OIFS # Restore original $IFS.
38 # This code snippet also by Heiner Steven.
39
40
42 # Setting the $IFS variable within the loop itself
43 #+ eliminates the need for storing the original $IFS
44 #+ in a temporary variable.
45 # Thanks, Dim Segebart, for pointing this out.
46 echo "-----
47 echo "List of all users:"
48
49 while IFS=: read name passwd uid gid fullname ignore
50 do
51 echo "$name ($fullname)"
52 done </etc/passwd # I/O redirection.
53
54 echo
55 echo "\$IFS still $IFS"
56
57 exit 0
```

Yet, piping the output of <u>cat</u> seems to work.

```
1 cat file1 file2 |
2 while read line
3 do
4 echo $line
5 done
```

However, as Bjön Eriksson shows:

Example 14-8. Problems reading from a pipe

```
1 #!/bin/sh
 2 # readpipe.sh
 3 # This example contributed by Bjon Eriksson.
 5 last="(null)"
 6 cat $0 |
 7 while read line
 8 do
9 echo "{$line}"
10 last=$line
11 done
12 printf "\nAll done, last:$last\n"
13
14 exit 0 # End of code.
# (Partial) output of script follows.
         # The 'echo' supplies extra brackets.
16
19
20 ./readpipe.sh
21
22 {#!/bin/sh}
23 {last="(null)"}
24 {cat $0 |}
25 {while read line}
26 {do}
27 {echo "{$line}"}
28 {last=$line}
29 {done}
30 {printf "nAll done, last:$lastn"}
31
32
33 All done, last: (null)
35 The variable (last) is set within the subshell but unset outside.
```

The *gendiff* script, usually found in /usr/bin on many Linux distros, pipes the output of <u>find</u> to a *while read* construct.

```
1 find $1 \( -name "*$2" -o -name ".*$2" \) -print |
2 while read f; do
3 . . .
```

it is possible to *paste* text into the input field of a *read*. See Example A-39.

Filesystem

The familiar **cd** change directory command finds use in scripts where execution of a command requires being in a specified directory.

```
1 (cd /source/directory && tar cf - . ) | (cd /dest/directory && tar xpvf -)

[from the previously cited example by Alan Cox]
```

The -P (physical) option to **cd** causes it to ignore symbolic links.

cd - changes to <u>\$OLDPWD</u>, the previous working directory.

The **cd** command does not function as expected when presented with two forward slashes.

```
bash$ cd //
bash$ pwd
//
```

The output should, of course, be /. This is a problem both from the command line and in a script.

pwd

Print Working Directory. This gives the user's (or script's) current directory (see <u>Example 14-9</u>). The effect is identical to reading the value of the builtin variable <u>\$PWD</u>.

pushd, popd, dirs

This command set is a mechanism for bookmarking working directories, a means of moving back and forth through directories in an orderly manner. A pushdown stack is used to keep track of directory names. Options allow various manipulations of the directory stack.

pushd dir-name pushes the path dir-name onto the directory stack and simultaneously changes the current working directory to dir-name

popd removes (pops) the top directory path name off the directory stack and simultaneously changes the current working directory to that directory popped from the stack.

dirs lists the contents of the directory stack (compare this with the <u>\$DIRSTACK</u> variable). A successful **pushd** or **popd** will automatically invoke **dirs**.

Scripts that require various changes to the current working directory without hard-coding the directory name changes can make good use of these commands. Note that the implicit \$DIRSTACK array variable, accessible from within a script, holds the contents of the directory stack.

Example 14-9. Changing the current working directory

```
1 #!/bin/bash
2
3 dir1=/usr/local
4 dir2=/var/spool
5
6 pushd $dir1
7 # Will do an automatic 'dirs' (list directory stack to stdout).
8 echo "Now in directory `pwd`." # Uses back-quoted 'pwd'.
9
10 # Now, do some stuff in directory 'dir1'.
11 pushd $dir2
12 echo "Now in directory `pwd`."
```

```
13
14 # Now, do some stuff in directory 'dir2'.
15 echo "The top entry in the DIRSTACK array is $DIRSTACK."
16 popd
17 echo "Now back in directory `pwd`."
18
19 # Now, do some more stuff in directory 'dir1'.
20 popd
21 echo "Now back in original working directory `pwd`."
22
23 exit 0
24
25 # What happens if you don't 'popd' -- then exit the script?
26 # Which directory do you end up in? Why?
```

Variables

let

The **let** command carries out arithmetic operations on variables. In many cases, it functions as a less complex version of <u>expr</u>.

Example 14-10. Letting let do arithmetic.

```
1 #!/bin/bash
 3 echo
 5 let a=11
                   # Same as 'a=11'
                    # Equivalent to let "a = a + 5"
 6 let a=a+5
                    # (Double quotes and spaces make it more readable.)
 8 echo "11 + 5 = $a" # 16
11 echo "\"\a\" (=16) left-shifted 3 places = a"
12
                    # 128
13
14 let "a /= 4"
                # Equivalent to let "a = a / 4"
15 echo "128 / 4 = $a" # 32
17 let "a -= 5" # Equivalent to let "a = a - 5"
18 echo "32 - 5 = a" # 27
19
20 let "a *= 10"  # Equivalent to let "a = a * 10"
21 echo "27 * 10 = $a" # 270
2.2
23 let "a %= 8" # Equivalent to let "a = a % 8"
24 echo "270 modulo 8 = $a (270 / 8 = 33, remainder $a)"
25
                    # 6
26
27 echo
28
29 exit 0
```

eval

eval arg1 [arg2] ... [argN]

Combines the arguments in an expression or list of expressions and *evaluates* them. Any variables contained within the expression are expanded. The result translates into a command. This can be useful for code generation from the command line or within a script.

```
bash$ process=xterm
bash$ show_process="eval ps ax | grep $process"
bash$ $show_process

1867 tty1 S 0:02 xterm
2779 tty1 S 0:00 xterm
2886 pts/1 S 0:00 grep xterm
```

Each invocation of eval forces a re-evaluation of its arguments.

Example 14-11. Showing the effect of eval

```
1 #!/bin/bash
 2 # Exercising "eval" ...
 4 y=`eval ls -l` # Similar to y=`ls -l`
 5 echo $y #+ but linefeeds removed because "echoed" variable is unquoted.
 6 echo
 7 echo "$y"
                # Linefeeds preserved when variable is quoted.
 9 echo; echo
10
11 y='eval df' # Similar to y='df'
12 echo $y #+ but linefeeds removed.
13
14 # When LF's not preserved, it may make it easier to parse output,
15 #+ using utilities such as "awk".
16
17 echo
18 echo "-----"
19 echo
20
21
22 # Now, showing how to do something useful with "eval" . . .
23 # (Thank you, E. Choroba!)
24
25 version=3.4
                 # Can we split the version into major and minor
                 #+ part in one command?
27 echo "version = $version"
                                   # Replaces '.' in version by ';minor='
28 eval major=${version/./;minor=}
                                    # The substitution yields '3; minor=4'
29
30
                                    #+ so eval does minor=4, major=3
31 echo Major: $major, minor: $minor # Major: 3, minor: 4
```

Example 14-12. Echoing the command-line parameters

```
1 #!/bin/bash
 2 # echo-params.sh
 4 # Call this script with a few command line parameters.
 5 # For example:
        sh echo-params.sh first second third fourth fifth
 8 params=$#
                        # Number of command-line parameters.
9 param=1
                        # Start at first command-line param.
10
11 while [ "$param" -le "$params" ]
12 do
   echo -n "Command line parameter "
13
   echo -n \$$param # Gives only the *name* of variable.
14
       ^^^
                        # $1, $2, $3, etc.
15 #
                        # Why?
16
                        # \$ escapes the first "$"
17
                        #+ so it echoes literally,
18
19
                        #+ and $param dereferences "$param" . . .
20
                        #+ . . . as expected.
   echo -n " = "
21
22 eval echo \$$param # Gives the *value* of variable.
23 # ^^^^
                        # The "eval" forces the *evaluation*
24
                        #+ of \$$
25
                        #+ as an indirect variable reference.
26
27 (( param ++ ))
                        # On to the next.
28 done
29
30 exit $?
31
32 # =======
33
34 $ sh echo-params.sh first second third fourth fifth
35 Command line parameter $1 = first
36 Command line parameter $2 = second
37 Command line parameter $3 = third
38 Command line parameter $4 = fourth
39 Command line parameter $5 = fifth
```

Example 14-13. Forcing a log-off

```
1 #!/bin/bash
 2 # Killing ppp to force a log-off.
 4 # Script should be run as root user.
 6 killppp="eval kill -9 `ps ax | awk '/ppp/ { print $1 }'`"
7 #
                         ---- process ID of ppp ---
8
9 $killppp
                             # This variable is now a command.
1.0
11
12 # The following operations must be done as root user.
14 chmod 666 /dev/ttyS3  # Restore read+write permissions, or else what?
15 # Since doing a SIGKILL on ppp changed the permissions on the serial port,
16 #+ we restore permissions to previous state.
17
18 rm /var/lock/LCK..ttyS3  # Remove the serial port lock file. Why?
19
20 # Note:
```

```
21 # Depending on the hardware and even the kernel version,
22 #+ the modem port on your machine may be different --
23 #+ /dev/ttyS1 or /dev/ttyS2.
24
25 exit 0
26
27 # Exercises:
28 # ------
29 # 1) Have script check whether root user is invoking it.
30 # 2) Do a check on whether the process to be killed
31 #+ is actually running before attempting to kill it.
32 # 3) Write an alternate version of this script based on 'fuser':
33 #+ if [ fuser -s /dev/modem ]; then . . .
```

Example 14-14. A version of rot13

```
1 #!/bin/bash
 2 # A version of "rot13" using 'eval'.
 3 # Compare to "rot13.sh" example.
 5 setvar_rot_13()
                                # "rot13" scrambling
   local varname=$1 varvalue=$2
    eval $varname='$(echo "$varvalue" | tr a-z n-za-m)'
 9 }
10
11
12 setvar_rot_13 var "foobar" # Run "foobar" through rot13.
13 echo $var
                               # sbbone
14
15 setvar_rot_13 var "$var"
                              # Run "sbbone" through rot13.
16
                               # Back to original variable.
17 echo $var
                                # foobar
18
19 # This example by Stephane Chazelas.
20 # Modified by document author.
2.1
22 exit 0
```

Rory Winston contributed the following instance of how useful eval can be.

Example 14-15. Using eval to force variable substitution in a Perl script

```
16 #
           ====
17
18 That works fine, and gives the expected substitution:
my $WEBROOT = /usr/local/webroot;
2.0
2.1
22 ### Correction applied to original example by Paulo Marcel Coelho Aragao.
```

1 The eval command can be risky, and normally should be avoided when there exists a reasonable alternative. An eval \$COMMANDS executes the contents of COMMANDS, which may contain such unpleasant surprises as rm -rf *. Running an eval on unfamiliar code written by persons unknown is living dangerously.

set

The **set** command changes the value of internal script variables/options. One use for this is to toggle option flags which help determine the behavior of the script. Another application for it is to reset the positional parameters that a script sees as the result of a command (set `command`). The script can then parse the fields of the command output.

Example 14-16. Using *set* with positional parameters

```
1 #!/bin/bash
 3 # script "set-test"
 5 # Invoke this script with three command line parameters,
 6 # for example, "./set-test one two three".
 8 echo
 9 echo "Positional parameters before set \`uname -a\` :"
10 echo "Command-line argument #1 = $1"
11 echo "Command-line argument #2 = $2"
12 echo "Command-line argument #3 = $3"
15 set `uname -a` # Sets the positional parameters to the output
        # of the command `uname -a`
16
17
            # unknown
18 echo $_
19 # Flags set in script.
21 echo "Positional parameters after set \`uname -a\` :"
22 # $1, $2, $3, etc. reinitialized to result of `uname -a`
23 echo "Field #1 of 'uname -a' = $1"
24 echo "Field #2 of 'uname -a' = $2"
25 echo "Field #3 of 'uname -a' = $3"
26 echo ---
                 # ---
27 echo $_
28 echo
29
30 exit 0
```

More fun with positional parameters.

Example 14-17. Reversing the positional parameters

```
1 #!/bin/bash
2 # revposparams.sh: Reverse positional parameters.
```

```
3 # Script by Dan Jacobson, with stylistic revisions by document author.
 5
 6 set a\ b c d\ e;
7 # ^ ^
                     Spaces escaped
                     Spaces not escaped
9 OIFS=$IFS; IFS=:;
10 #
                    Saving old IFS and setting new one.
11
12 echo
13
14 until [ $# -eq 0 ]
15 do # Step through positional parameters.
16 echo "### k0 = "$k"" # Before
17 k=\$1:\$k; # Append each pos param to loop variable.
18 # ^
19 echo "### k = "$k""  # After
   echo
20
21 shift;
22 done
23
24 set $k # Set new positional parameters.
25 echo -
26 echo $# # Count of positional parameters.
27 echo -
28 echo
29
30 for i # Omitting the "in list" sets the variable -- i --
         #+ to the positional parameters.
33 echo $i # Display new positional parameters.
34 done
35
36 IFS=$OIFS # Restore IFS.
37
38 # Question:
39 # Is it necessary to set an new IFS, internal field separator,
40 #+ in order for this script to work properly?
41 # What happens if you don't? Try it.
42 \# And, why use the new IFS -- a colon -- in line 17,
43 #+ to append to the loop variable?
44 # What is the purpose of this?
45
46 exit 0
47
48 $ ./revposparams.sh
49
50 ### k0 =
51 ### k = a b
53 \# \# \# k0 = a b
54 ### k = c a b
55
56 \# \# \# k0 = cab
57 ### k = d e c a b
58
59 -
60 3
61 -
62
63 d e
64 c
65 a b
```

Invoking **set** without any options or arguments simply lists all the <u>environmental</u> and other variables that have been initialized.

```
bash$ set
AUTHORCOPY=/home/bozo/posts
BASH=/bin/bash
BASH_VERSION=$'2.05.8(1)-release'
...
XAUTHORITY=/home/bozo/.Xauthority
_=/etc/bashrc
variable22=abc
variable23=xzy
```

Using **set** with the — option explicitly assigns the contents of a variable to the positional parameters. If no variable follows the — it *unsets* the positional parameters.

Example 14-18. Reassigning the positional parameters

```
1 #!/bin/bash
 3 variable="one two three four five"
 5 set -- $variable
 6 # Sets positional parameters to the contents of "$variable".
8 first_param=$1
9 second_param=$2
10 shift; shift  # Shift past first two positional params.
11 # shift 2 also works.
12 remaining_params="$*"
13
14 echo
15 echo "first parameter = $first_param"  # one
16 echo "second parameter = $second_param"  # two
17 echo "remaining parameters = $remaining_params" # three four five
19 echo; echo
20
21 # Again.
22 set -- $variable
23 first_param=$1
24 second_param=$2
25 echo "first parameter = $first_param"
26 echo "second parameter = $second_param"
                                                    # one
29
31 # Unsets positional parameters if no variable specified.
33 first_param=$1
34 second_param=$2
37
38 exit 0
```

See also Example 10-2 and Example 15-54.

unset

The **unset** command deletes a shell variable, effectively setting it to *null*. Note that this command does not affect positional parameters.

```
bash$ unset PATH
bash$ echo $PATH
bash$
```

Example 14-19. "Unsetting" a variable

```
1 #!/bin/bash
 2 # unset.sh: Unsetting a variable.
 4 variable=hello
                                        # Initialized.
 5 echo "variable = $variable"
 7 unset variable
                                        # Unset.
                                        # Same effect as: variable=
9 echo "(unset) variable = $variable" # $variable is null.
10
11 if [ -z "$variable" ]
                                        # Try a string-length test.
12 then
   echo "\$variable has zero length."
14 fi
15
16 exit 0
```

export

The **export** [2] command makes available variables to all child processes of the running script or shell. One important use of the **export** command is in <u>startup files</u>, to initialize and make accessible environmental variables to subsequent user processes.

1 Unfortunately, there is no way to export variables back to the parent process, to the process that called or invoked the script or shell.

Example 14-20. Using *export* to pass a variable to an embedded *awk* script

```
1 #!/bin/bash
 3 # Yet another version of the "column totaler" script (col-totaler.sh)
 4 #+ that adds up a specified column (of numbers) in the target file.
 5 \# This uses the environment to pass a script variable to 'awk' . . .
 6 #+ and places the awk script in a variable.
9 ARGS=2
10 E_WRONGARGS=65
11
12 if [ $# -ne "$ARGS" ] # Check for proper no. of command line args.
13 then
   echo "Usage: `basename $0` filename column-number"
14
15
    exit $E_WRONGARGS
16 fi
17
18 filename=$1
19 column_number=$2
20
21 #==== Same as original script, up to this point =====#
2.2.
23 export column_number
```

it is possible to initialize and export variables in the same operation, as in **export** var1=xxx.

However, as Greg Keraunen points out, in certain situations this may have a different effect than setting a variable, then exporting it.

```
bash$ export var=(a b); echo ${var[0]}
  (a b)

bash$ var=(a b); export var; echo ${var[0]}
a
```

declare, typeset

The <u>declare</u> and <u>typeset</u> commands specify and/or restrict properties of variables.

readonly

Same as <u>declare -r</u>, sets a variable as read-only, or, in effect, as a constant. Attempts to change the variable fail with an error message. This is the shell analog of the *C* language **const** type qualifier.

getopts

This powerful tool parses command-line arguments passed to the script. This is the Bash analog of the <u>getopt</u> external command and the *getopt* library function familiar to *C* programmers. It permits passing and concatenating multiple options [3] and associated arguments to a script (for example **scriptname -abc -e /usr/local**).

The **getopts** construct uses two implicit variables. \$OPTIND is the argument pointer (*OPTion INDex*) and \$OPTARG (*OPTion ARGument*) the (optional) argument attached to an option. A colon following the option name in the declaration tags that option as having an associated argument.

A **getopts** construct usually comes packaged in a <u>while loop</u>, which processes the options and arguments one at a time, then increments the implicit \$OPTIND variable to step to the next.

- 1. The arguments passed from the command line to the script must be preceded by a minus (–). It is the prefixed that lets **getopts** recognize command-line arguments as *options*. In fact, **getopts** will not process arguments without the prefixed –, and will terminate option processing at the first argument encountered lacking them.
- 2. The **getopts** template differs slightly from the standard **while** loop, in that it lacks condition brackets.

3. The **getopts** construct replaces the deprecated <u>getopt</u> external command.

```
1 while getopts ":abcde:fg" Option
 2 # Initial declaration.
 3 # a, b, c, d, e, f, and g are the options (flags) expected.
 4 # The : after option 'e' shows it will have an argument passed with it.
    case $Option in
 7
     a ) # Do something with variable 'a'.
 8
      b ) # Do something with variable 'b'.
10
      e) # Do something with 'e', and also with $OPTARG,
          # which is the associated argument passed with option 'e'.
11
12
1.3
    g ) # Do something with variable 'g'.
14 esac
15 done
16 shift $(($OPTIND - 1))
17 # Move argument pointer to next.
18
19 # All this is not nearly as complicated as it looks <grin>.
```

Example 14-21. Using getopts to read the options/arguments passed to a script

```
1 #!/bin/bash
 2 # Exercising getopts and OPTIND
 3 \# Script modified 10/09/03 at the suggestion of Bill Gradwohl.
 6 # Here we observe how 'getopts' processes command line arguments to script.
 7 # The arguments are parsed as "options" (flags) and associated arguments.
9 # Try invoking this script with
10 # 'scriptname -mn'
11 # 'scriptname -oq qOption' (qOption can be some arbitrary string.)
12 # 'scriptname -qXXX -r'
13 #
14 # 'scriptname -qr' - Unexpected result, takes "r" as the argument to option "q"
15 # 'scriptname -q -r' - Unexpected result, same as above
16 # 'scriptname -mnop -mnop' - Unexpected result
17 # (OPTIND is unreliable at stating where an option came from).
19 # If an option expects an argument ("flag:"), then it will grab
20 #+ whatever is next on the command line.
21
22 NO_ARGS=0
23 E_OPTERROR=65
2.4
25 if [ $# -eq "$NO_ARGS" ] # Script invoked with no command-line args?
   echo "Usage: `basename $0` options (-mnopqrs)"
                      # Exit and explain usage, if no argument(s) given.
28 exit $E_OPTERROR
29 fi
30 # Usage: scriptname -options
31 # Note: dash (-) necessary
32
33
34 while getopts ":mnopq:rs" Option
35 do
36 case $Option in
     m ) echo "Scenario #1: option -m- [OPTIND=${OPTIND}]";;
37
38
     n | o ) echo "Scenario #2: option - $Option- [OPTIND=${OPTIND}]";;
     p ) echo "Scenario #3: option -p- [OPTIND=${OPTIND}]";;
39
```

```
40
           ) echo "Scenario #4: option -q-\
41 with argument \"$OPTARG\" [OPTIND=${OPTIND}]";;
     # Note that option 'q' must have an associated argument,
      #+ otherwise it falls through to the default.
     r | s ) echo "Scenario #5: option -$Option-";;
           ) echo "Unimplemented option chosen.";;  # DEFAULT
46 esac
47 done
48
49 shift $(($OPTIND - 1))
50 # Decrements the argument pointer so it points to next argument.
51 \# $1 now references the first non option item supplied on the command line
52 #+ if one exists.
53
54 exit 0
56 #
      As Bill Gradwohl states,
57 # "The getopts mechanism allows one to specify: scriptname -mnop -mnop
58 #+ but there is no reliable way to differentiate what came from where
59 #+ by using OPTIND."
```

Script Behavior

source, . (<u>dot</u> command)

This command, when invoked from the command line, executes a script. Within a script, a **source file-name** loads the file file-name. *Sourcing* a file (dot-command) *imports* code into the script, appending to the script (same effect as the **#include** directive in a *C* program). The net result is the same as if the "sourced" lines of code were physically present in the body of the script. This is useful in situations when multiple scripts use a common data file or function library.

Example 14-22. "Including" a data file

```
1 #!/bin/bash
 3 . data-file
                 # Load a data file.
4 # Same effect as "source data-file", but more portable.
 6 # The file "data-file" must be present in current working directory,
 7 #+ since it is referred to by its 'basename'.
9 # Now, reference some data from that file.
11 echo "variable1 (from data-file) = $variable1"
12 echo "variable3 (from data-file) = $variable3"
14 let "sum = $variable2 + $variable4"
15 echo "Sum of variable2 + variable4 (from data-file) = $sum"
16 echo "message1 (from data-file) is \"$message1\""
17 # Note:
                                     escaped quotes
19 print_message This is the message-print function in the data-file.
20
21
22 exit 0
```

File data-file for Example 14-22, above. Must be present in same directory.

```
1 # This is a data file loaded by a script.
2 # Files of this type may contain variables, functions, etc.
3 # It may be loaded with a 'source' or '.' command by a shell script.
4
```

```
5 # Let's initialize some variables.
7 variable1=22
8 variable2=474
9 variable3=5
10 variable4=97
11
12 message1="Hello, how are you?"
13 message2="Enough for now. Goodbye."
1 4
15 print_message ()
16 {
17 # Echoes any message passed to it.
18
   if [ -z "$1" ]
19
20
    then
   return 1
2.1
      # Error, if argument missing.
23
24
25
   echo
26
   until [ -z "$1" ]
2.7
28 do
29 # Step through arguments passed to function.
30
     echo -n "$1"
31
     # Echo args one at a time, suppressing line feeds.
     echo -n " "
33
     # Insert spaces between words.
34
     shift
35
     # Next one.
36
   done
37
38
   echo
39
40
    return 0
41 }
```

If the *sourced* file is itself an executable script, then it will run, then return control to the script that called it. A *sourced* executable script may use a <u>return</u> for this purpose.

Arguments may be (optionally) passed to the *sourced* file as <u>positional parameters</u>.

```
1 source $filename $arg1 arg2
```

It is even possible for a script to *source* itself, though this does not seem to have any practical applications.

Example 14-23. A (useless) script that sources itself

```
1 #!/bin/bash
2 # self-source.sh: a script sourcing itself "recursively."
3 # From "Stupid Script Tricks," Volume II.
4
5 MAXPASSCNT=100 # Maximum number of execution passes.
6
7 echo -n "$pass_count "
8 # At first execution pass, this just echoes two blank spaces,
9 #+ since $pass_count still uninitialized.
10
11 let "pass_count += 1"
```

```
12 # Assumes the uninitialized variable $pass_count
13 #+ can be incremented the first time around.
14 # This works with Bash and pdksh, but
15 #+ it relies on non-portable (and possibly dangerous) behavior.
16 # Better would be to initialize $pass_count to 0 before incrementing.
18 while [ "$pass_count" -le $MAXPASSCNT ]
19 do
20 . $0 # Script "sources" itself, rather than calling itself.
            # ./$0 (which would be true recursion) doesn't work here. Why?
21
22 done
2.3
24 # What occurs here is not actually recursion,
25 #+ since the script effectively "expands" itself, i.e.,
26 #+ generates a new section of code
27 #+ with each pass through the 'while' loop',
28 # with each 'source' in line 20.
30 # Of course, the script interprets each newly 'sourced' "#!" line
31 #+ as a comment, and not as the start of a new script.
33 echo
34
35 exit 0  # The net effect is counting from 1 to 100.
36 # Very impressive.
37
38 # Exercise:
39 # --
40 # Write a script that uses this trick to actually do something useful.
```

exit

Unconditionally terminates a script. [4] The **exit** command may optionally take an integer argument, which is returned to the shell as the <u>exit status</u> of the script. It is good practice to end all but the simplest scripts with an **exit** 0, indicating a successful run.

- If a script terminates with an **exit** lacking an argument, the exit status of the script is the exit status of the last command executed in the script, not counting the **exit**. This is equivalent to an **exit** \$?.
- An exit command may also be used to terminate a subshell.

exec

This shell builtin replaces the current process with a specified command. Normally, when the shell encounters a command, it <u>forks off</u> a child process to actually execute the command. Using the **exec** builtin, the shell does not fork, and the command *exec*'ed replaces the shell. When used in a script, therefore, it forces an exit from the script when the **exec**'ed command terminates. [5]

Example 14-24. Effects of exec

Example 14-25. A script that exec's itself

```
1 #!/bin/bash
2 # self-exec.sh
4 echo
 6 echo "This line appears ONCE in the script, yet it keeps echoing."
7 echo "The PID of this instance of the script is still $$."
       Demonstrates that a subshell is not forked off.
10 echo "======== Hit Ctl-C to exit =========""
11
12 sleep 1
13
14 exec $0
            # Spawns another instance of this same script
1.5
            #+ that replaces the previous one.
16
17 echo "This line will never echo!" # Why not?
19 exit 99
                                     # Will not exit here!
20
                                     # Exit code will not be 99!
```

An **exec** also serves to <u>reassign file descriptors</u>. For example, **exec <zzz-file** replaces stdin with the file zzz-file.

shopt

This command permits changing *shell options* on the fly (see Example 24-1 and Example 24-2). It often appears in the Bash startup files, but also has its uses in scripts. Needs version 2 or later of Bash.

```
1 shopt -s cdspell
2 # Allows minor misspelling of directory names with 'cd'
3
4 cd /hpme # Oops! Mistyped '/home'.
5 pwd # /home
6 # The shell corrected the misspelling.
```

caller

Putting a **caller** command inside a <u>function</u> echoes to stdout information about the *caller* of that function.

```
1 #!/bin/bash
3 function1 ()
    # Inside function1 ().
 6
    caller 0 # Tell me about it.
 7 }
9 function1 # Line 9 of script.
10
11 # 9 main test.sh
12 # ^
                      Line number that the function was called from.
13 # ^^^^
                     Invoked from "main" part of script.
14 #
          ^^^^^
                    Name of calling script.
15
```

```
16 caller 0  # Has no effect because it's not inside a function.
```

A **caller** command can also return *caller* information from a script <u>sourced</u> within another script. Analogous to a function, this is a "subroutine call."

You may find this command useful in debugging.

Commands

true

A command that returns a successful (zero) exit status, but does nothing else.

```
bash$ true
bash$ echo $?
0
```

```
1 # Endless loop
2 while true # alias for ":"
3 do
4   operation-1
5   operation-2
6   ...
7   operation-n
8   # Need a way to break out of loop or script will hang.
9 done
```

false

A command that returns an unsuccessful exit status, but does nothing else.

```
bash$ false
bash$ echo $?
1
```

```
1 # Testing "false"
 2 if false
 3 then
 4 echo "false evaluates \"true\""
 5 else
 6 echo "false evaluates \"false\""
 7 fi
 8 # false evaluates "false"
 9
1.0
11 # Looping while "false" (null loop)
12 while false
13 do
14 # The following code will not execute.
15 operation-1
16 operation-2
17
18 operation-n
19 # Nothing happens!
20 done
```

type [cmd]

Similar to the <u>which</u> external command, **type cmd** identifies "cmd." Unlike **which**, **type** is a Bash builtin. The useful -a option to **type** identifies keywords and builtins, and also locates system commands with identical names.

```
bash$ type '['
[ is a shell builtin
```

```
bash$ type -a '['
[ is a shell builtin
[ is /usr/bin/[

bash$ type type
type is a shell builtin
```

hash [cmds]

Record the path name of specified commands -- in the shell hash table [6] -- so the shell or script will not need to search the PATH on subsequent calls to those commands. When **hash** is called with no arguments, it simply lists the commands that have been hashed. The -r option resets the hash table.

bind

The **bind** builtin displays or modifies *readline* [7] key bindings.

help

Gets a short usage summary of a shell builtin. This is the counterpart to whatis, but for builtins.

```
bash$ help exit
exit: exit [n]
   Exit the shell with a status of N. If N is omitted, the exit status
   is that of the last command executed.
```

14.1. Job Control Commands

Certain of the following job control commands take a "job identifier" as an argument. See the <u>table</u> at end of the chapter.

jobs

Lists the jobs running in the background, giving the job number. Not as useful as ps.

It is all too easy to confuse *jobs* and *processes*. Certain <u>builtins</u>, such as **kill**, **disown**, and **wait** accept either a job number or a process number as an argument. The <u>fg</u>, <u>bg</u> and **jobs** commands accept only a job number.

"1" is the job number (jobs are maintained by the current shell). "1384" is the <u>PID</u> or process ID number (processes are maintained by the system). To kill this job/process, either a **kill %1** or a **kill 1384** works.

Thanks, S.C.

disown

Remove job(s) from the shell's table of active jobs.

fg, bg

The **fg** command switches a job running in the background into the foreground. The **bg** command restarts a suspended job, and runs it in the background. If no job number is specified, then the **fg** or **bg** command acts upon the currently running job.

wait

Suspend script execution until all jobs running in background have terminated, or until the job number or process ID specified as an option terminates. Returns the <u>exit status</u> of waited-for command.

You may use the **wait** command to prevent a script from exiting before a background job finishes executing (this would create a dreaded <u>orphan process</u>).

Example 14-26. Waiting for a process to finish before proceeding

```
1 #!/bin/bash
 3 ROOT_UID=0 # Only users with $UID 0 have root privileges.
 4 E NOTROOT=65
 5 E_NOPARAMS=66
 7 if [ "$UID" -ne "$ROOT_UID" ]
9 echo "Must be root to run this script."
    # "Run along kid, it's past your bedtime."
   exit $E_NOTROOT
11
12 fi
13
14 if [ -z "$1" ]
15 then
16 echo "Usage: `basename $0` find-string"
   exit $E_NOPARAMS
18 fi
19
```

```
20
21 echo "Updating 'locate' database..."
22 echo "This may take a while."
23 updatedb /usr & # Must be run as root.
24
25 wait
26 # Don't run the rest of the script until 'updatedb' finished.
27 # You want the the database updated before looking up the file name.
28
29 locate $1
30
31 # Without the 'wait' command, in the worse case scenario,
32 #+ the script would exit while 'updatedb' was still running,
33 #+ leaving it as an orphan process.
34
35 exit 0
```

Optionally, wait can take a job identifier as an argument, for example, wait %1 or wait \$PPID. See the job id table.

i Within a script, running a command in the background with an ampersand (&) may cause the script to hang until **ENTER** is hit. This seems to occur with commands that write to stdout. It can be a major annoyance.

```
1 #!/bin/bash
2 # test.sh
3
4 ls -1 &
5 echo "Done."
bash$ ./test.sh
Done.
[bozo@localhost test-scripts]$ total 1
-rwxr-xr-x 1 bozo bozo 34 Oct 11 15:09 test.sh
-
```

As Walter Brameld IV explains it:

As far as I can tell, such scripts don't actually hang. It just seems that they do because the background command writes text to the console after the prompt. The user gets the impression that the prompt was never displayed. Here's the sequence of events:

- 1. Script launches background command.
- 2. Script exits.
- 3. Shell displays the prompt.
- 4. Background command continues running and writing text to the console.
- 5. Background command finishes.
- 6. User doesn't see a prompt at the bottom of the output, thinks script is hanging.

Placing a **wait** after the background command seems to remedy this.

```
1 #!/bin/bash
2 # test.sh
3
4 ls -1 &
```

```
5 echo "Done."
6 wait
bash$ ./test.sh
Done.
[bozo@localhost test-scripts]$ total 1
-rwxr-xr-x 1 bozo bozo 34 Oct 11 15:09 test.sh
```

Redirecting the output of the command to a file or even to /dev/null also takes care of this problem.

suspend

This has a similar effect to **Control-Z**, but it suspends the shell (the shell's parent process should resume it at an appropriate time).

logout

Exit a login shell, optionally specifying an exit status.

times

Gives statistics on the system time used in executing commands, in the following form:

```
0m0.020s 0m0.020s
```

This capability is of very limited value, since it is uncommon to profile and benchmark shell scripts.

kill

Forcibly terminate a process by sending it an appropriate *terminate* signal (see Example 16-6).

Example 14-27. A script that kills itself

```
1 #!/bin/bash
2 # self-destruct.sh
4 kill $$ # Script kills its own process here.
           # Recall that "$$" is the script's PID.
 7 echo "This line will not echo."
8 # Instead, the shell sends a "Terminated" message to stdout.
10 exit 0 # Normal exit? No!
11
12 # After this script terminates prematurely,
13 #+ what exit status does it return?
14 #
15 # sh self-destruct.sh
16 # echo $?
17 # 143
18 #
19 # 143 = 128 + 15
20 # TERM signal
```

kill -1 lists all the <u>signals</u> (as does the file /usr/include/asm/signal.h). A **kill** -9 is a *sure kill*, which will usually terminate a process that stubbornly refuses to die with a plain **kill**. Sometimes, a **kill** -15 works. A "zombie" process, that is, a child process that has terminated, but that the <u>parent process</u> has not (yet) killed, cannot be killed by a logged-on user -- you can't kill something that is already dead -- but **init** will generally clean it up sooner or later.

killall

The **killall** command kills a running process by *name*, rather than by <u>process ID</u>. If there are multiple instances of a particular command running, then doing a *killall* on that command will terminate them *all*.

command

The **command** directive disables aliases and functions for the command immediately following it.

bash\$ command 1s

This is one of three shell directives that effect script command processing. The others are <u>builtin</u> and <u>enable</u>.

builtin

Invoking **builtin BUILTIN_COMMAND** runs the command *BUILTIN_COMMAND* as a shell <u>builtin</u>, temporarily disabling both functions and external system commands with the same name.

enable

This either enables or disables a shell builtin command. As an example, $enable -n \ kill$ disables the shell builtin \underline{kill} , so that when Bash subsequently encounters kill, it invokes the external command $/ \underline{bin/kill}$.

The -a option to *enable* lists all the shell builtins, indicating whether or not they are enabled. The -f filename option lets *enable* load a <u>builtin</u> as a shared library (DLL) module from a properly compiled object file. [8].

autoload

This is a port to Bash of the *ksh* autoloader. With **autoload** in place, a function with an *autoload* declaration will load from an external file at its first invocation. [9] This saves system resources.

Note that *autoload* is not a part of the core Bash installation. It needs to be loaded in with enable -f (see above).

Table 14-1. Job identifiers

Notation	Meaning
%N	Job number [N]
%S	Invocation (command line) of job begins with string S
%?S	Invocation (command line) of job contains within it string <i>S</i>
ે ે	"current" job (last job stopped in foreground or started in background)
응+	"current" job (last job stopped in foreground or started in background)
%-	Last job
\$!	Last background process

Notes

- [1] An exception to this is the <u>time</u> command, listed in the official Bash documentation as a keyword.
- [2] To Export information is to make it available in a larger context. See also scope.
- [3] A option is an argument that acts as a flag, switching script behaviors on or off. The argument associated with a particular option indicates the behavior that the option (flag) switches on or off.
- [4] Technically, an **exit** only terminates the process (or shell) in which it is running, *not* the *parent process*.
- [5] Unless the **exec** is used to <u>reassign file descriptors</u>.
- [6]

Hashing is a method of creating lookup keys for data stored in a table. The *data items themselves* are "scrambled" to create keys, using one of a number of simple mathematical *algorithms* (methods, or recipes).

An advantage of *hashing* is that it is fast. A disadvantage is that "collisions" -- where a single key maps to more than one data item -- are possible.

For examples of hashing see Example A-22 and Example A-23.

- [7] The *readline* library is what Bash uses for reading input in an interactive shell.
- [8] The C source for a number of loadable builtins is typically found in the /usr/share/doc/bash-?.??/functions directory.

Note that the -f option to **enable** is not portable to all systems.

[9] The same effect as **autoload** can be achieved with <u>typeset -fu</u>.

Chapter 15. External Filters, Programs and Commands

Standard UNIX commands make shell scripts more versatile. The power of scripts comes from coupling system commands and shell directives with simple programming constructs.

15.1. Basic Commands

The first commands a novice learns

ls

The basic file "list" command. It is all too easy to underestimate the power of this humble command. For example, using the -R, recursive option, **Is** provides a tree-like listing of a directory structure. Other useful options are -S, sort listing by file size, -t, sort by file modification time, -b, show escape characters, and -i, show file inodes (see Example 15-4).

The *ls* command returns a non-zero <u>exit status</u> when attempting to list a non-existent file.

```
bash$ ls abc
ls: abc: No such file or directory

bash$ echo $?
2
```

Example 15-1. Using *ls* to create a table of contents for burning a CDR disk

```
1 #!/bin/bash
 2 \# ex40.sh (burn-cd.sh)
 3 # Script to automate burning a CDR.
 6 SPEED=2
                    # May use higher speed if your hardware supports it.
 7 IMAGEFILE=cdimage.iso
 8 CONTENTSFILE=contents
9 DEVICE=cdrom
10 # DEVICE="0,0"
                    For older versions of cdrecord
11 DEFAULTDIR=/opt # This is the directory containing the data to be burned.
12
                    # Make sure it exists.
13
                   # Exercise: Add a test for this.
14
15 # Uses Joerg Schilling's "cdrecord" package:
16 # http://www.fokus.fhg.de/usr/schilling/cdrecord.html
17
18 # If this script invoked as an ordinary user, may need to suid cdrecord
19 #+ chmod u+s /usr/bin/cdrecord, as root.
20 # Of course, this creates a security hole, though a relatively minor one.
21
22 if [ -z "$1" ]
23 then
24 IMAGE_DIRECTORY=$DEFAULTDIR
25 # Default directory, if not specified on command line.
26 else
27
      IMAGE_DIRECTORY=$1
28 fi
2.9
30 # Create a "table of contents" file.
31 ls -lrf $IMAGE_DIRECTORY > $IMAGE_DIRECTORY/$CONTENTSFILE
32 # The "l" option gives a "long" file listing.
33 # The "R" option makes the listing recursive.
34 # The "F" option marks the file types (directories get a trailing /).
35 echo "Creating table of contents."
37 # Create an image file preparatory to burning it onto the CDR.
38 mkisofs -r -o $IMAGEFILE $IMAGE_DIRECTORY
```

```
39 echo "Creating ISO9660 file system image ($IMAGEFILE)."
40
41 # Burn the CDR.
42 echo "Burning the disk."
43 echo "Please be patient, this will take a while."
44 cdrecord -v -isosize speed=$SPEED dev=$DEVICE $IMAGEFILE
45
46 exit $?
```

cat, tac

cat, an acronym for *concatenate*, lists a file to stdout. When combined with redirection (> or >>), it is commonly used to concatenate files.

```
1 # Uses of 'cat'
2 cat filename  # Lists the file.
3
4 cat file.1 file.2 file.3 > file.123 # Combines three files into one.
```

The -n option to **cat** inserts consecutive numbers before all lines of the target file(s). The -b option numbers only the non-blank lines. The -v option echoes nonprintable characters, using $^{\land}$ notation. The -s option squeezes multiple consecutive blank lines into a single blank line.

See also Example 15-27 and Example 15-23.

In a pipe, it may be more efficient to redirect the stdin to a file, rather than to cat the file.

```
1 cat filename | tr a-z A-Z
2
3 tr a-z A-Z < filename  # Same effect, but starts one less process,
4  #+ and also dispenses with the pipe.</pre>
```

tac, is the inverse of *cat*, listing a file backwards from its end.

rev

reverses each line of a file, and outputs to stdout. This does not have the same effect as **tac**, as it preserves the order of the lines, but flips each one around (mirror image).

```
bash$ cat file1.txt
This is line 1.
This is line 2.

bash$ tac file1.txt
This is line 2.
This is line 1.

bash$ rev file1.txt
.1 enil si sihT
.2 enil si sihT
```

ср

This is the file copy command. **cp file1 file2** copies file1 to file2, overwriting file2 if it already exists (see Example 15-6).

Particularly useful are the -a archive flag (for copying an entire directory tree), the -u update flag (which prevents overwriting identically-named newer files), and the -r and -R recursive flags.

```
1 cp -u source_dir/* dest_dir
```

```
2 # "Synchronize" dest_dir to source_dir
3 #+ by copying over all newer and not previously existing files.
```

mv

This is the file *move* command. It is equivalent to a combination of **cp** and **rm**. It may be used to move multiple files to a directory, or even to rename a directory. For some examples of using **mv** in a script, see Example 9-20 and Example A-2.

When used in a non-interactive script, mv takes the -f (*force*) option to bypass user input.

When a directory is moved to a preexisting directory, it becomes a subdirectory of the destination directory.

```
bash$ mv source_directory target_directory

bash$ ls -lF target_directory
total 1
drwxrwxr-x 2 bozo bozo 1024 May 28 19:20 source_directory/
```

rm

Delete (remove) a file or files. The -f option forces removal of even readonly files, and is useful for bypassing user input in a script.

The *rm* command will, by itself, fail to remove filenames beginning with a dash. Why? Because *rm* sees a dash-prefixed filename as an *option*.

```
bash$ rm -badname
rm: invalid option -- b
Try `rm --help' for more information.
```

One clever workaround is to precede the filename with a " -- " (the *end-of-options* flag).

```
bash$ rm -- -badname
```

Another method to is to preface the filename to be removed with a dot-slash.

```
bash$ rm ./-badname
```

When used with the recursive flag -r, this command removes files all the way down the directory tree from the current directory. A careless **rm** -**rf** * can wipe out a big chunk of a directory structure.

rmdir

Remove directory. The directory must be empty of all files -- including "invisible" *dotfiles* [1] -- for this command to succeed.

mkdir

Make directory, creates a new directory. For example, **mkdir** -**p project/programs/December** creates the named directory. The -p option automatically creates any necessary parent directories.

chmod

Changes the attributes of an existing file or directory (see Example 14-13).

```
1 chmod +x filename
2 # Makes "filename" executable for all users.
3
4 chmod u+s filename
5 # Sets "suid" bit on "filename" permissions.
```

```
6 # An ordinary user may execute "filename" with same privileges as the file's owner.
7 # (This does not apply to shell scripts.)
```

```
1 chmod 644 filename
2 # Makes "filename" readable/writable to owner, readable to others
3 # (octal mode).
4
5 chmod 444 filename
6 # Makes "filename" read-only for all.
7 # Modifying the file (for example, with a text editor)
8 #+ not allowed for a user who does not own the file (except for root),
9 #+ and even the file owner must force a file-save
10 #+ if she modifies the file.
11 # Same restrictions apply for deleting the file.
```

```
1 chmod 1777 directory-name
 2 # Gives everyone read, write, and execute permission in directory,
 3 #+ however also sets the "sticky bit".
 4 # This means that only the owner of the directory,
 5 #+ owner of the file, and, of course, root
 6 #+ can delete any particular file in that directory.
 8 chmod 111 directory-name
9 # Gives everyone execute-only permission in a directory.
10 # This means that you can execute and READ the files in that directory
11 #+ (execute permission necessarily includes read permission
12 #+ because you can't execute a file without being able to read it).
13 # But you can't list the files or search for them with the "find" command.
14 # These restrictions do not apply to root.
15
16 chmod 000 directory-name
17 # No permissions at all for that directory.
18 # Can't read, write, or execute files in it.
19 # Can't even list files in it or "cd" to it.
20 # But, you can rename (mv) the directory
21 #+ or delete it (rmdir) if it is empty.
22 # You can even symlink to files in the directory,
23 #+ but you can't read, write, or execute the symlinks.
24 # These restrictions do not apply to root.
```

chattr

Change file **attr**ibutes. This is analogous to **chmod** above, but with different options and a different invocation syntax, and it works only on an *ext2* filesystem.

One particularly interesting **chattr** option is i. A **chattr +i filename** marks the file as immutable. The file cannot be modified, linked to, or deleted, *not even by root*. This file attribute can be set or removed only by *root*. In a similar fashion, the a option marks the file as append only.

```
root# chattr +i file1.txt

root# rm file1.txt

rm: remove write-protected regular file `file1.txt'? y
rm: cannot remove `file1.txt': Operation not permitted
```

If a file has the s (secure) attribute set, then when it is deleted its block is zeroed out on the disk.

If a file has the u (undelete) attribute set, then when it is deleted, its contents can still be retrieved (undeleted).

If a file has the c (compress) attribute set, then it will automatically be compressed on writes to disk,

and uncompressed on reads.

The file attributes set with **chattr** do not show in a file listing (**ls -l**).

ln

Creates links to pre-existings files. A "link" is a reference to a file, an alternate name for it. The **ln** command permits referencing the linked file by more than one name and is a superior alternative to aliasing (see Example 4-6).

The **In** creates only a reference, a pointer to the file only a few bytes in size.

The In command is most often used with the -s, symbolic or "soft" link flag. Advantages of using the -s flag are that it permits linking across file systems or to directories.

The syntax of the command is a bit tricky. For example: ln -s oldfile newfile links the previously existing oldfile to the newly created link, newfile.

1 If a file named newfile has previously existed, an error message will result.

Which type of link to use?

As John Macdonald explains it:

Both of these [types of links] provide a certain measure of dual reference -- if you edit the contents of the file using any name, your changes will affect both the original name and either a hard or soft new name. The differences between them occurs when you work at a higher level. The advantage of a hard link is that the new name is totally independent of the old name -- if you remove or rename the old name, that does not affect the hard link, which continues to point to the data while it would leave a soft link hanging pointing to the old name which is no longer there. The advantage of a soft link is that it can refer to a different file system (since it is just a reference to a file name, not to actual data). And, unlike a hard link, a symbolic link can refer to a directory.

Links give the ability to invoke a script (or any other type of executable) with multiple names, and having that script behave according to how it was invoked.

Example 15-2. Hello or Good-bye

```
1 #!/bin/bash
 2 # hello.sh: Saying "hello" or "goodbye"
             depending on how script is invoked.
 5 # Make a link in current working directory ($PWD) to this script:
 6 # ln -s hello.sh goodbye
 7 # Now, try invoking this script both ways:
8 # ./hello.sh
9 # ./goodbye
10
11
12 HELLO_CALL=65
13 GOODBYE_CALL=66
15 if [ $0 = "./goodbye" ]
17 echo "Good-bye!"
```

```
# Some other goodbye-type commands, as appropriate.
exit $GOODBYE_CALL
fi
call
```

man, info

These commands access the manual and information pages on system commands and installed utilities. When available, the *info* pages usually contain more detailed descriptions than do the *man* pages.

Notes

[1]

Dotfiles are files whose names begin with a dot, such as \sim /.Xdefaults. Such filenames do not appear in a normal **ls** listing (although an **ls -a** will show them), and they cannot be deleted by an accidental **rm -rf***. Dotfiles are generally used as setup and configuration files in a user's home directory.

Commands for more advanced users

find

```
-exec COMMAND \:
```

Carries out *COMMAND* on each file that **find** matches. The command sequence terminates with; (the ";" is <u>escaped</u> to make certain the shell passes it to **find** literally, without interpreting it as a special character).

```
bash$ find ~/ -name '*.txt'
/home/bozo/.kde/share/apps/karm/karmdata.txt
/home/bozo/misc/irmeyc.txt
/home/bozo/test-scripts/1.txt
```

If COMMAND contains {}, then **find** substitutes the full path name of the selected file for "{}".

```
1 find ~/ -name 'core*' -exec rm {} \;
2 # Removes all core dump files from user's home directory.
```

```
1 find /home/bozo/projects -mtime 1
 2 # Lists all files in /home/bozo/projects directory tree
 3 #+ that were modified within the last day.
 5 # mtime = last modification time of the target file
 6 # ctime = last status change time (via 'chmod' or otherwise)
 7 # atime = last access time
9 DIR=/home/bozo/junk_files
10 find "$DIR" -type f -atime +5 -exec rm \{\}\
11 #
12 # Curly brackets are placeholder for the path name output by "find."
14 # Deletes all files in "/home/bozo/junk_files"
15 #+ that have not been accessed in at least 5 days.
17 # "-type filetype", where
18 # f = regular file
19 # d = directory
20 # 1 = symbolic link, etc.
21 # (The 'find' manpage and info page have complete listings.)
```

```
1 find /etc -exec grep '[0-9][0-9]*[.][0-9][0-9]*[.][0-9][0-9]*' {} \;
2
3 # Finds all IP addresses (xxx.xxx.xxx) in /etc directory files.
4 # There a few extraneous hits. Can they be filtered out?
5
6 # Possibly by:
7
8 find /etc -type f -exec cat '{}' \; | tr -c '.[:digit:]' '\n' \
9 | grep '^[^.][^.]*\.[^.][^.]*\.[^.][^.]*\.[^.][^.]*$'
10 #
11 # [:digit:] is one of the character classes
12 #+ introduced with the POSIX 1003.2 standard.
13
14 # Thanks, Stéphane Chazelas.
```

Example 15-3. Badname, eliminate file names in current directory containing bad characters and whitespace.

```
1 #!/bin/bash
 2 # badname.sh
 3 # Delete filenames in current directory containing bad characters.
 5 for filename in *
 6 do
    badname=`echo "filename" | sed -n /[\+\{\;\"\\=\?~\(\)\<\>\&\*\|\$]/p`
 7
 8 # badname=`echo "$filename" | sed -n '/[+{;"\=?~()<>&*|$]/p'` also works.
 9 # Deletes files containing these nasties: + { ; " \ = ? ~ ( ) < > & * | $
   rm $badname 2>/dev/null
12 #
          ^^^^^^^ Error messages deep-sixed.
13 done
14
15 # Now, take care of files containing all manner of whitespace.
16 find . -name "* *" -exec rm -f {} \;
17 # The path name of the file that _find_ finds replaces the "{}".
18 # The '\' ensures that the ';' is interpreted literally, as end of command.
19
20 exit 0
21
23 # Commands below this line will not execute because of _exit_ command.
25 # An alternative to the above script:
26 find . -name '*[+{;"\\=?~()<>&*|$ ]*' -maxdepth 0 \
27 -exec rm -f '{}' \;
28 # The "-maxdepth 0" option ensures that _find_ will not search
29 #+ subdirectories below $PWD.
30
31 # (Thanks, S.C.)
```

Example 15-4. Deleting a file by its inode number

```
1 #!/bin/bash
 2 # idelete.sh: Deleting a file by its inode number.
 4 # This is useful when a filename starts with an illegal character,
 5 #+ such as ? or -.
7 ARGCOUNT=1
                                  # Filename arg must be passed to script.
8 E_WRONGARGS=70
9 E_FILE_NOT_EXIST=71
10 E_CHANGED_MIND=72
11
12 if [ $# -ne "$ARGCOUNT" ]
   echo "Usage: `basename $0` filename"
15
   exit $E_WRONGARGS
16 fi
18 if [ ! -e "$1" ]
19 then
   echo "File \""$1"\" does not exist."
```

```
21 exit $E_FILE_NOT_EXIST
22 fi
2.3
24 inum=`ls -i | grep "$1" | awk '{print $1}'`
25 # inum = inode (index node) number of file
27 # Every file has an inode, a record that holds its physical address info.
29
30 echo; echo -n "Are you absolutely sure you want to delete \"\$1\" (y/n)? "
31 # The '-v' option to 'rm' also asks this.
32 read answer
33 case "$answer" in
34 [nN]) echo "Changed your mind, huh?"
    exit $E_CHANGED_MIND
       ;;
37 *) echo "Deleting file \"$1\".";;
38 esac
39
40 find . -inum $inum -exec rm {} \;
41 #
42 # Curly brackets are placeholder
43 #+ for text cutt
44 echo "File "\"$1"\" deleted!"
45
46 exit 0
```

The **find** command also works without the -exec option.

```
1 #!/bin/bash
2 # Find suid root files.
3 # A strange suid file might indicate a security hole,
4 #+ or even a system intrusion.
5
6 directory="/usr/sbin"
7 # Might also try /sbin, /bin, /usr/bin, /usr/local/bin, etc.
8 permissions="+4000" # suid root (dangerous!)
9
10
11 for file in $( find "$directory" -perm "$permissions")
12 do
13  ls -ltF --author "$file"
14 done
```

See Example 15-29, Example 3-4, and Example 10-9 for scripts using **find**. Its <u>manpage</u> provides more detail on this complex and powerful command.

xargs

A filter for feeding arguments to a command, and also a tool for assembling the commands themselves. It breaks a data stream into small enough chunks for filters and commands to process. Consider it as a powerful replacement for <u>backquotes</u>. In situations where <u>command substitution</u> fails with a too many arguments error, substituting **xargs** often works. [1] Normally, **xargs** reads from stdin or from a pipe, but it can also be given the output of a file.

The default command for **xargs** is <u>echo</u>. This means that input piped to **xargs** may have linefeeds and other whitespace characters stripped out.

```
bash$ ls -l
total 0
-rw-rw-r-- 1 bozo bozo 0 Jan 29 23:58 file1
-rw-rw-r-- 1 bozo bozo 0 Jan 29 23:58 file2
```

```
bash$ ls -l | xargs
total 0 -rw-rw-r-- 1 bozo bozo 0 Jan 29 23:58 file1 -rw-rw-r-- 1 bozo bozo 0 Jan...

bash$ find ~/mail -type f | xargs grep "Linux"
./misc:User-Agent: slrn/0.9.8.1 (Linux)
./sent-mail-jul-2005: hosted by the Linux Documentation Project.
./sent-mail-jul-2005: (Linux Documentation Project Site, rtf version)
./sent-mail-jul-2005: Subject: Criticism of Bozo's Windows/Linux article
./sent-mail-jul-2005: while mentioning that the Linux ext2/ext3 filesystem
. . .
```

ls | **xargs** -**p** -**l gzip gzips** every file in current directory, one at a time, prompting before each operation.

Note that *xargs* processes the arguments passed to it sequentially, *one at a time*.

```
bash$ find /usr/bin | xargs file
/usr/bin: directory
/usr/bin/foomatic-ppd-options: perl script text executable
. . .
```

- An interesting *xargs* option is -n *NN*, which limits to *NN* the number of arguments passed.
 - 1s | xargs -n 8 echo lists the files in the current directory in 8 columns.
- Another useful option is -0, in combination with **find** -**print0** or **grep** -1**Z**. This allows handling arguments containing whitespace or quotes.

```
find / -type f -print0 | xargs -0 grep -liwZ GUI | xargs
-0 rm -f
grep -rliwZ GUI / | xargs -0 rm -f
```

Either of the above will remove any file containing "GUI". (Thanks, S.C.)

Or:

Example 15-5. Logfile: Using xargs to monitor system log

```
1 #!/bin/bash
2
3 # Generates a log file in current directory
4 # from the tail end of /var/log/messages.
5
6 # Note: /var/log/messages must be world readable
7 # if this script invoked by an ordinary user.
8 # #root chmod 644 /var/log/messages
```

```
9
10 LINES=5
11
12 ( date; uname -a ) >>logfile
13 # Time and machine name
14 echo -----
15 tail -n $LINES /var/log/messages | xargs | fmt -s >>logfile
16 echo >>logfile
17 echo >>logfile
18
19 exit 0
20
21 # Note:
22 #
23 # As Frank Wang points out,
24 #+ unmatched quotes (either single or double quotes) in the source file
25 #+ may give xargs indigestion.
27 # He suggests the following substitution for line 15:
28 # tail -n $LINES /var/log/messages | tr -d "\"'" | xargs | fmt -s >>logfile
29
30
31
32 # Exercise:
33 # -----
34 # Modify this script to track changes in /var/log/messages at intervals
35 #+ of 20 minutes.
36 # Hint: Use the "watch" command.
```

As in **find**, a curly bracket pair serves as a placeholder for replacement text.

Example 15-6. Copying files in current directory to another

```
1 #!/bin/bash
 2 # copydir.sh
 4 # Copy (verbose) all files in current directory ($PWD)
 5 #+ to directory specified on command line.
7 E_NOARGS=65
9 if [-z "$1"] # Exit if no argument given.
10 then
   echo "Usage: `basename $0` directory-to-copy-to"
12 exit $E_NOARGS
13 fi
14
15 ls . | xargs -i -t cp ./{} $1
                ^^ ^^
16 #
17 # -t is "verbose" (output command line to stderr) option.
18 # -i is "replace strings" option.
19 # {} is a placeholder for output text.
20 # This is similar to the use of a curly bracket pair in "find."
21 #
22 # List the files in current directory (ls .),
23 #+ pass the output of "ls" as arguments to "xargs" (-i -t options),
24 #+ then copy (cp) these arguments ({}) to new directory ($1).
25 #
26 # The net result is the exact equivalent of
27 #+ cp * $1
28 #+ unless any of the filenames has embedded "whitespace" characters.
```

Example 15-7. Killing processes by name

```
1 #!/bin/bash
 2 # kill-byname.sh: Killing processes by name.
 3 # Compare this script with kill-process.sh.
 5 # For instance,
 6 #+ try "./kill-byname.sh xterm" --
7 #+ and watch all the xterms on your desktop disappear.
9 # Warning:
10 # ----
11 # This is a fairly dangerous script.
12 # Running it carelessly (especially as root)
13 #+ can cause data loss and other undesirable effects.
1 4
15 E_BADARGS=66
16
17 if test -z "$1" # No command line arg supplied?
   echo "Usage: `basename $0` Process(es)_to_kill"
19
20
    exit $E_BADARGS
21 fi
22
23
24 PROCESS_NAME="$1"
25 ps ax | grep "$PROCESS_NAME" | awk '{print $1}' | xargs -i kill {} 2&>/dev/null
26 #
27
28 # -----
29 # Notes:
30 # -i is the "replace strings" option to xargs.
31 # The curly brackets are the placeholder for the replacement.
32 # 2&>/dev/null suppresses unwanted error messages.
33 #
34 # Can grep "$PROCESS_NAME" be replaced by pidof "$PROCESS_NAME"?
35 # ----
36
37 exit $?
38
39 # The "killall" command has the same effect as this script,
40 #+ but using it is not quite as educational.
```

Example 15-8. Word frequency analysis using xargs

```
1 #!/bin/bash
2 # wf2.sh: Crude word frequency analysis on a text file.
3
4 # Uses 'xargs' to decompose lines of text into single words.
5 # Compare this example to the "wf.sh" script later on.
6
7
8 # Check for input file on command line.
9 ARGS=1
10 E_BADARGS=65
11 E_NOFILE=66
12
```

```
13 if [ $# -ne "$ARGS" ]
14 # Correct number of arguments passed to script?
15 then
16 echo "Usage: `basename $0` filename"
17 exit $E_BADARGS
18 fi
19
20 if [ ! -f "$1" ]  # Check if file exists.
21 then
22 echo "File \"$1\" does not exist."
23 exit $E_NOFILE
24 fi
2.5
2.6
2.7
29 cat "$1" | xargs -n1 | \
30 # List the file, one word per line.
31 tr A-Z a-z | \
32 # Shift characters to lowercase.
33 sed -e 's/\.//g' -e 's/\,//g' -e 's/ \wedge
34 /g' | \
35 # Filter out periods and commas, and
36 #+ change space between words to linefeed,
37 sort | uniq -c | sort -nr
38 # Finally prefix occurrence count and sort numerically.
41 # This does the same job as the "wf.sh" example,
42 #+ but a bit more ponderously, and it runs more slowly (why?).
43
44 exit 0
```

expr

All-purpose expression evaluator: Concatenates and evaluates the arguments according to the operation given (arguments must be separated by spaces). Operations may be arithmetic, comparison, string, or logical.

```
expr 3 + 5
returns 8

expr 5 % 3
returns 2

expr 1 / 0
returns the error message, expr: division by zero

Illegal arithmetic operations not allowed.
```

expr 5 * 3
returns 15

The multiplication operator must be escaped when used in an arithmetic expression with **expr**.

```
y=`expr $y + 1`
```

Increment a variable, with the same effect as let y=y+1 and y=\$((\$y+1)). This is an example of <u>arithmetic expansion</u>.

z=`expr substr \$string \$position \$length`

Extract substring of \$length characters, starting at \$position.

```
1 #!/bin/bash
3 # Demonstrating some of the uses of 'expr'
6 echo
7
8 # Arithmetic Operators
9 # -----
10
11 echo "Arithmetic Operators"
12 echo
13 a=`expr 5 + 3`
14 \text{ echo } "5 + 3 = $a"
15
16 a=`expr $a + 1`
17 echo
18 \text{ echo "a} + 1 = \$a"
19 echo "(incrementing a variable)"
20
21 a=`expr 5 % 3`
22 # modulo
23 echo
24 \text{ echo } "5 \text{ mod } 3 = $a"
25
26 echo
27 echo
29 # Logical Operators
30 # -----
31
32 # Returns 1 if true, 0 if false,
33 #+ opposite of normal Bash convention.
35 echo "Logical Operators"
36 echo
37
38 x=24
39 y=25
40 b='expr $x = $y'  # Test equality.
41 echo "b = $b"  # 0 ($x -ne $y)
42 echo
43
44 a=3
45 b=`expr $a \> 10`
46 echo 'b=`expr $a \> 10`, therefore...'
47 echo "If a > 10, b = 0 (false)"
48 echo "b = $b"
                    # 0 (3!-gt 10)
49 echo
50
51 b=`expr $a \< 10`
52 echo "If a < 10, b = 1 (true)"
53 echo "b = $b"
                           # 1 (3 -lt 10)
54 echo
55 # Note escaping of operators.
57 b=`expr $a \<= 3`
58 echo "If a <= 3, b = 1 (true)"
59 echo "b = $b"
                    # 1 (3 -le 3)
60 # There is also a "\>=" operator (greater than or equal to).
61
62
63 echo
64 echo
65
66
```

```
68 # String Operators
69 # -----
70
71 echo "String Operators"
72 echo
73
74 a=1234zipper43231
75 echo "The string being operated upon is \"$a\"."
77 # length: length of string
78 b=`expr length $a`
79 echo "Length of \"$a\" is $b."
80
81 # index: position of first character in substring
           that matches a character in string
83 b=`expr index $a 23`
84 echo "Numerical position of first \"2\" in \"$a\" is \"$b\"."
85
86 # substr: extract substring, starting position & length specified
87 b=`expr substr $a 2 6`
88 echo "Substring of \"$a\", starting at position 2,\
89 and 6 chars long is \"$b\"."
90
91
92 # The default behavior of the 'match' operations is to
93 #+ search for the specified match at the ***beginning*** of the string.
95 #
          uses Regular Expressions
96 b=`expr match "$a" '[0-9]*'`
                                           # Numerical count.
97 echo Number of digits at the beginning of \"$a\" is $b.
+ trigger substring match.
100 echo "The digits at the beginning of \"$a\" are \"$b\"."
101
102 echo
103
104 exit 0
```

! The : operator can substitute for **match**. For example, $b=\ensuremath{\text{expr}}$ \$\frac{1}{2} \text{ is the exact equivalent of } \frac{1}{2} \text{ expr match } \frac{1}{2} \text{ in the above listing.}

```
1 #!/bin/bash
3 echo
4 echo "String operations using \"expr \$string : \" construct"
6 echo
8 a=1234zipper5FLIPPER43231
10 echo "The string being operated upon is \"`expr \$a" : \(.*\)'`\"."
     Escaped parentheses grouping operator.
11 #
                                               == ==
12
13 #
        ********
14 #+
          Escaped parentheses
15 #+
           match a substring
        *******
16 #
17
19 # If no escaped parentheses...
20 #+ then 'expr' converts the string operand to an integer.
2.1
22 echo "Length of \"$a\" is `expr "$a" : '.*'`." # Length of string
```

```
24 echo "Number of digits at the beginning of \"$a\" is `expr "$a" : '[0-9]*'`."
27
28 echo
29
30 echo "The digits at the beginning of \"$a\" are `expr "$a" : '([0-9]*)'."
32 echo "The first 7 characters of \"a" are `expr "a" : '\(.....\)'`."
34 # Again, escaped parentheses force a substring match.
35 #
36 echo "The last 7 characters of \"a" are `expr "a" : '.*\(.....\)'`."
38 # (actually means skip over one or more of any characters until specified
39 #+ substring)
40
41 echo
42
43 exit 0
```

The above script illustrates how **expr** uses the *escaped parentheses* -- \(... \) -- grouping operator in tandem with <u>regular expression</u> parsing to match a substring. Here is a another example, this time from "real life."

```
1 # Strip the whitespace from the beginning and end.
2 LRFDATE=`expr "$LRFDATE" : '[[:space:]]*\(.*\)[[:space:]]*$'`
3
4 # From Peter Knowles' "booklistgen.sh" script
5 #+ for converting files to Sony Librie/PRS-50X format.
6 # (http://booklistgensh.peterknowles.com)
```

<u>Perl</u>, <u>sed</u>, and <u>awk</u> have far superior string parsing facilities. A short **sed** or **awk** "subroutine" within a script (see <u>Section 33.3</u>) is an attractive alternative to **expr**.

See Section 9.2 for more on using **expr** in string operations.

Notes

Commands

<u>Prev</u>

And even when *xargs* is not strictly necessary, it can speed up execution of a command involving batch-processing of multiple files.

<u>Prev</u> <u>Home</u> <u>Next</u> External Filters, Programs and <u>Up</u> Time / Date Commands

Advanced Bash-Scripting Guide: An in-depth exploration of the art of shell scripting

Chapter 15. External Filters, Programs and Commands

<u>Next</u>

15.3. Time / Date Commands

Time/date and timing

date

Simply invoked, **date** prints the date and time to stdout. Where this command gets interesting is in its formatting and parsing options.

Example 15-10. Using date

```
1 #!/bin/bash
 2 # Exercising the 'date' command
 4 echo "The number of days since the year's beginning is `date +%j`."
 5 # Needs a leading '+' to invoke formatting.
 6 # %j gives day of year.
 8 echo "The number of seconds elapsed since 01/01/1970 is `date +%s`."
 9 # %s yields number of seconds since "UNIX epoch" began,
10 #+ but how is this useful?
11
12 prefix=temp
13 suffix=$(date +%s) # The "+%s" option to 'date' is GNU-specific.
14 filename=$prefix.$suffix
15 echo $filename
16 # It's great for creating "unique" temp filenames,
17 #+ even better than using $$.
19 # Read the 'date' man page for more formatting options.
21 exit 0
```

The -u option gives the UTC (Universal Coordinated Time).

```
bash$ date
Fri Mar 29 21:07:39 MST 2002

bash$ date -u
Sat Mar 30 04:07:42 UTC 2002
```

This option facilitates calculating the time between different dates.

Example 15-11. Date calculations

```
1 #!/bin/bash
2 # date-calc.sh
3 # Author: Nathan Coulter
4 # Used in ABS Guide with permission (thanks!).
5
6 MPHR=60 # Minutes per hour.
7 HPD=24 # Hours per day.
8
9 diff () {
10         printf '%s' $(( $(date -u -d"$TARGET" +%s) - $(date -u -d"$CURRENT" +%s)))
12 # %d = day of month.
```

```
13 }
14
15
16 CURRENT=$ (date -u -d '2007-09-01 17:30:24' '+%F %T.%N %Z')
17 TARGET=$ (date -u -d'2007-12-25 12:30:00' '+%F %T.%N %Z')
18 # %F = full date, %T = %H:%M:%S, %N = nanoseconds, %Z = time zone.
19
20 printf '\nIn 2007, %s ' \
         "$(date -d"$CURRENT +
2.1
          $(( $(diff) /$MPHR /$MPHR /$HPD / 2 )) days" '+%d %B')"
23 # %B = name of month
                                            ^ halfway
24 printf 'was halfway between %s ' "$(date -d"$CURRENT" '+%d %B')"
25 printf 'and %s\n' "$(date -d"$TARGET" '+%d %B')"
27 printf '\nOn %s at %s, there were\n' \
          $(date -u -d"$CURRENT" +%F) $(date -u -d"$CURRENT" +%T)
29 DAYS=$(($(diff) / $MPHR / $MPHR / $HPD ))
30 CURRENT=$(date -d"$CURRENT +$DAYS days" '+%F %T.%N %Z')
31 HOURS=$(( $(diff) / $MPHR / $MPHR ))
32 CURRENT=$(date -d"$CURRENT +$HOURS hours" '+%F %T.%N %Z')
33 MINUTES=$(( $(diff) / $MPHR ))
34 CURRENT=$(date -d"$CURRENT +$MINUTES minutes" '+%F %T.%N %Z')
35 printf '%s days, %s hours, ' "$DAYS" "$HOURS"
36 printf '%s minutes, and %s seconds ' "$MINUTES" "$(diff)"
37 printf 'until Christmas Dinner!\n\n'
39 # Exercise:
41 # Rewrite the diff () function to accept passed parameters,
42 #+ rather than using global variables.
```

The *date* command has quite a number of *output* options. For example %N gives the nanosecond portion of the current time. One interesting use for this is to generate six-digit random integers.

There are many more options (try **man date**).

See also Example 3-4.

zdump

Time zone dump: echoes the time in a specified time zone.

```
bash$ zdump EST
EST Tue Sep 18 22:09:22 2001 EST
```

time

Outputs very verbose timing statistics for executing a command.

time 1s -1 / gives something like this:

```
0.00user 0.01system 0:00.05elapsed 16%CPU (0avgtext+0avgdata 0maxresident)k 0inputs+0outputs (149major+27minor)pagefaults 0swaps
```

See also the very similar times command in the previous section.

As of <u>version 2.0</u> of Bash, **time** became a shell reserved word, with slightly altered behavior in a pipeline.

touch

Utility for updating access/modification times of a file to current system time or other specified time, but also useful for creating a new file. The command **touch zzz** will create a new file of zero length, named zzz, assuming that zzz did not previously exist. Time-stamping empty files in this way is useful for storing date information, for example in keeping track of modification times on a project.

- The **touch** command is equivalent to : >> **newfile** or >> **newfile** (for ordinary files).
- Before doing a <u>cp -u</u> (*copy/update*), use **touch** to update the time stamp of files you don't wish overwritten.

As an example, if the directory /home/bozo/tax_audit contains the files spreadsheet-051606.data, spreadsheet-051706.data, and spreadsheet-051806.data, then doing a touch spreadsheet*.data will protect these files from being overwritten by files with the same names during a cp -u /home/bozo/financial_info/spreadsheet*data/home/bozo/tax_audit.

at

The **at** job control command executes a given set of commands at a specified time. Superficially, it resembles <u>cron</u>, however, **at** is chiefly useful for one-time execution of a command set.

at 2pm January 15 prompts for a set of commands to execute at that time. These commands should be shell-script compatible, since, for all practical purposes, the user is typing in an executable shell script a line at a time. Input terminates with a Ctl-D.

Using either the -f option or input redirection (<), **at** reads a command list from a file. This file is an executable shell script, though it should, of course, be noninteractive. Particularly clever is including the <u>run-parts</u> command in the file to execute a different set of scripts.

```
bash$ at 2:30 am Friday < at-jobs.list
job 2 at 2000-10-27 02:30
```

batch

The **batch** job control command is similar to **at**, but it runs a command list when the system load drops below .8. Like **at**, it can read commands from a file with the -f option.

The concept of *batch processing* dates back to the era of mainframe computers. It means running a set of commands without user intervention.

Prints a neatly formatted monthly calendar to stdout. Will do current year or a large range of past and future years.

sleep

This is the shell equivalent of a *wait loop*. It pauses for a specified number of seconds, doing nothing. It can be useful for timing or in processes running in the background, checking for a specific event every so often (polling), as in <u>Example 29-6</u>.

The **sleep** command defaults to seconds, but minute, hours, or days may also be specified.

```
1 sleep 3 h # Pauses 3 hours!
```

The <u>watch</u> command may be a better choice than **sleep** for running commands at timed intervals.

usleep

Microsleep (the *u* may be read as the Greek *mu*, or *micro*- prefix). This is the same as **sleep**, above, but "sleeps" in microsecond intervals. It can be used for fine-grained timing, or for polling an ongoing process at very frequent intervals.

```
1 usleep 30  # Pauses 30 microseconds.
```

This command is part of the Red Hat *initscripts / rc-scripts* package.

The **usleep** command does not provide particularly accurate timing, and is therefore unsuitable for critical timing loops.

hwclock, clock

The **hwclock** command accesses or adjusts the machine's hardware clock. Some options require *root* privileges. The /etc/rc.d/rc.sysinit startup file uses **hwclock** to set the system time from the hardware clock at bootup.

The **clock** command is a synonym for **hwclock**.

15.4. Text Processing Commands

Commands affecting text and text files

sort

File sort utility, often used as a filter in a pipe. This command sorts a *text stream* or file forwards or backwards, or according to various keys or character positions. Using the -m option, it merges presorted input files. The *info page* lists its many capabilities and options. See <u>Example 10-9</u>, <u>Example 10-10</u>, and <u>Example A-8</u>.

tsort

Topological sort, reading in pairs of whitespace-separated strings and sorting according to input patterns. The original purpose of **tsort** was to sort a list of dependencies for an obsolete version of the *ld* linker in an "ancient" version of UNIX.

The results of a *tsort* will usually differ markedly from those of the standard **sort** command, above.

uniq

This filter removes duplicate lines from a sorted file. It is often seen in a pipe coupled with sort.

```
1 cat list-1 list-2 list-3 | sort | uniq > final.list
2 # Concatenates the list files,
3 # sorts them,
4 # removes duplicate lines,
5 # and finally writes the result to an output file.
```

The useful -c option prefixes each line of the input file with its number of occurrences.

```
bash$ cat testfile
This line occurs only once.
This line occurs twice.
This line occurs twice.
This line occurs three times.
This line occurs three times.
This line occurs three times.

This line occurs three times.

bash$ uniq -c testfile

1 This line occurs only once.
2 This line occurs twice.
3 This line occurs three times.

bash$ sort testfile | uniq -c | sort -nr

3 This line occurs three times.
2 This line occurs twice.
1 This line occurs only once.
```

The **sort INPUTFILE** | **uniq -c** | **sort -nr** command string produces a *frequency of occurrence* listing on the INPUTFILE file (the -nr options to **sort** cause a reverse numerical sort). This template finds use in analysis of log files and dictionary lists, and wherever the lexical structure of a document needs to be examined.

Example 15-12. Word Frequency Analysis

```
1 #!/bin/bash
2 # wf.sh: Crude word frequency analysis on a text file.
3 # This is a more efficient version of the "wf2.sh" script.
4
5
```

```
6 # Check for input file on command line.
7 ARGS=1
8 E_BADARGS=65
9 E_NOFILE=66
11 if [ $# -ne "$ARGS" ] # Correct number of arguments passed to script?
13
   echo "Usage: `basename $0` filename"
14 exit $E_BADARGS
15 fi
16
17 if [ ! -f "$1" ]
                   # Check if file exists.
18 then
   echo "File \"$1\" does not exist."
19
20 exit $E_NOFILE
21 fi
2.2.
23
24
25 #####
26 # main ()
27 sed -e 's/\.//g' -e 's/\,//g' -e 's/ \
28 /g' "$1" | tr 'A-Z' 'a-z' | sort | uniq -c | sort -nr
29 #
                            _____
30 #
                             Frequency of occurrence
31
32 # Filter out periods and commas, and
33 #+ change space between words to linefeed,
34 #+ then shift characters to lowercase, and
35 #+ finally prefix occurrence count and sort numerically.
36
37 # Arun Giridhar suggests modifying the above to:
     . . . | sort | uniq -c | sort +1 [-f] | sort +0 -nr
39 # This adds a secondary sort key, so instances of
40 #+ equal occurrence are sorted alphabetically.
41 # As he explains it:
     "This is effectively a radix sort, first on the
43 #+ least significant column
44 #+ (word or string, optionally case-insensitive)
45 #+ and last on the most significant column (frequency)."
46 #
47 # As Frank Wang explains, the above is equivalent to
48 #+ . . . | sort | uniq -c | sort +0 -nr
49 #+ and the following also works:
50 #+ ... | sort | uniq -c | sort -k1nr -k
53 exit 0
55 # Exercises:
57 # 1) Add 'sed' commands to filter out other punctuation,
58 #+ such as semicolons.
59 \# 2) Modify the script to also filter out multiple spaces and
60 #+ other whitespace.
```

```
bash$ cat testfile

This line occurs only once.

This line occurs twice.

This line occurs three times.

This line occurs three times.

This line occurs three times.
```

```
bash$ ./wf.sh testfile
6 this
6 occurs
6 line
3 times
3 three
2 twice
1 only
1 once
```

expand, unexpand

The **expand** filter converts tabs to spaces. It is often used in a pipe.

The **unexpand** filter converts spaces to tabs. This reverses the effect of **expand**.

cut

A tool for extracting fields from files. It is similar to the **print \$N** command set in <u>awk</u>, but more limited. It may be simpler to use *cut* in a script than *awk*. Particularly important are the -d (delimiter) and -f (field specifier) options.

Using **cut** to obtain a listing of the mounted filesystems:

```
1 cut -d ' ' -f1,2 /etc/mtab
```

Using **cut** to list the OS and kernel version:

```
1 uname -a | cut -d" " -f1,3,11,12
```

Using **cut** to extract message headers from an e-mail folder:

```
bash$ grep '^Subject:' read-messages | cut -c10-80
Re: Linux suitable for mission-critical apps?
MAKE MILLIONS WORKING AT HOME!!!
Spam complaint
Re: Spam complaint
```

Using **cut** to parse a file:

```
1 # List all the users in /etc/passwd.
2
3 FILENAME=/etc/passwd
4
5 for user in $(cut -d: -f1 $FILENAME)
6 do
7   echo $user
8 done
9
10 # Thanks, Oleg Philon for suggesting this.
```

cut -d ' ' -f2,3 filename is equivalent to awk -F'[]' '{ print \$2, \$3 }'
filename

It is even possible to specify a linefeed as a delimiter. The trick is to actually embed a linefeed (**RETURN**) in the command sequence.

```
bash$ cut -d'
' -f3,7,19 testfile
This is line 3 of testfile.
This is line 7 of testfile.
This is line 19 of testfile.
```

Thank you, Jaka Kranje, for pointing this out.

See also Example 15-46.

paste

Tool for merging together different files into a single, multi-column file. In combination with <u>cut</u>, useful for creating system log files.

join

Consider this a special-purpose cousin of **paste**. This powerful utility allows merging two files in a meaningful fashion, which essentially creates a simple version of a relational database.

The **join** command operates on exactly two files, but pastes together only those lines with a common tagged field (usually a numerical label), and writes the result to stdout. The files to be joined should be sorted according to the tagged field for the matchups to work properly.

```
1 File: 1.data
2
3 100 Shoes
4 200 Laces
5 300 Socks
```

```
1 File: 2.data
2
3 100 $40.00
4 200 $1.00
5 300 $2.00
```

```
bash$ join 1.data 2.data
File: 1.data 2.data

100 Shoes $40.00
200 Laces $1.00
300 Socks $2.00
```

The tagged field appears only once in the output.

head

lists the beginning of a file to stdout. The default is 10 lines, but this can be changed. The command has a number of interesting options.

Example 15-13. Which files are scripts?

```
1 #!/bin/bash
 2 # script-detector.sh: Detects scripts within a directory.
 4 TESTCHARS=2
                # Test first 2 characters.
               # Scripts begin with a "sha-bang."
 5 SHABANG='#!'
 6
 7 for file in * # Traverse all the files in current directory.
 8 do
9 if [[ `head -c$TESTCHARS "$file"` = "$SHABANG" ]]
10 # head -c2
                                       #!
11 # The '-c' option to "head" outputs a specified
12 #+ number of characters, rather than lines (the default).
echo "File \"$file\" is a script."
     echo "File \"$file\" is *not* a script."
16
17 fi
18 done
19
20 exit 0
2.1
22 # Exercises:
```

```
23 # ------
24 # 1) Modify this script to take as an optional argument
25 #+ the directory to scan for scripts
26 #+ (rather than just the current working directory).
27 #
28 # 2) As it stands, this script gives "false positives" for
29 #+ Perl, awk, and other scripting language scripts.
30 # Correct this.
```

Example 15-14. Generating 10-digit random numbers

```
1 #!/bin/bash
2 # rnd.sh: Outputs a 10-digit random number
 4 # Script by Stephane Chazelas.
 6 head -c4 /dev/urandom | od -N4 -tu4 | sed -ne '1s/.* //p'
8
9 # ============ #
10
11 # Analysis
12 # -----
13
14 # head:
15 \# -c4 option takes first 4 bytes.
16
17 # od:
18 # -N4 option limits output to 4 bytes.
19 # -tu4 option selects unsigned decimal format for output.
20
21 # sed:
22 # -n option, in combination with "p" flag to the "s" command,
23 # outputs only matched lines.
2.4
2.5
26
27 # The author of this script explains the action of 'sed', as follows.
29 # head -c4 /dev/urandom | od -N4 -tu4 | sed -ne '1s/.* //p'
30 # -----> |
32 # Assume output up to "sed" ----> |
33 # is 0000000 1198195154\n
35 # sed begins reading characters: 0000000 1198195154\n.
36 # Here it finds a newline character,
37 \text{ } \# + \text{ so it is ready to process the first line } (0000000 1198195154).
38 # It looks at its <range><action>s. The first and only one is
39
40 # range action
41 # 1
              s/.* //p
42
43 # The line number is in the range, so it executes the action:
44 #+ tries to substitute the longest string ending with a space in the line
45 \# ("0000000 ") with nothing (//), and if it succeeds, prints the result
46 # ("p" is a flag to the "s" command here, this is different
47 #+ from the "p" command).
49 # sed is now ready to continue reading its input. (Note that before
50 #+ continuing, if -n option had not been passed, sed would have printed
51 #+ the line once again).
```

```
52
53 \ \# Now, sed reads the remainder of the characters, and finds the
54 #+ end of the file.
55 # It is now ready to process its 2nd line (which is also numbered '$' as
56 #+ it's the last one).
57 # It sees it is not matched by any <range>, so its job is done.
59 # In few word this sed commmand means:
60 # "On the first line only, remove any character up to the right-most space,
61 #+ then print it."
63 # A better way to do this would have been:
             sed -e 's/.* //;q'
64 #
66 # Here, two <range><action>s (could have been written
            sed -e 's/.* //' -e q):
67 #
68
69 #
     range
                             action
70 # nothing (matches line) s/.* //
71 # nothing (matches line) q (quit)
72
73 # Here, sed only reads its first line of input.
74 # It performs both actions, and prints the line (substituted) before
75 \#+ quitting (because of the "q" action) since the "-n" option is not passed.
76
77 # ============= #
79 # An even simpler altenative to the above one-line script would be:
80 # head -c4 /dev/urandom| od -An -tu4
81
82 exit 0
```

See also Example 15-38.

tail

lists the (tail) end of a file to stdout. The default is 10 lines, but this can be changed. Commonly used to keep track of changes to a system logfile, using the -f option, which outputs lines appended to the file.

Example 15-15. Using tail to monitor the system log

```
1 #!/bin/bash
2
3 filename=sys.log
4
5 cat /dev/null > $filename; echo "Creating / cleaning out file."
6 # Creates file if it does not already exist,
7 #+ and truncates it to zero length if it does.
8 # : > filename and > filename also work.
9
10 tail /var/log/messages > $filename
11 # /var/log/messages must have world read permission for this to work.
12
13 echo "$filename contains tail end of system log."
14
15 exit 0
```

To list a specific line of a text file, <u>pipe</u> the output of **head** to **tail -n 1**. For example **head -n 8 database.txt | tail -n 1** lists the 8th line of the file database.txt.

To set a variable to a given block of a text file:

```
1 var=$(head -n $m $filename | tail -n $n)
2
3 # filename = name of file
4 # m = from beginning of file, number of lines to end of block
5 # n = number of lines to set variable to (trim from end of block)
```

Newer implementations of **tail** deprecate the older **tail** -\$LINES filename usage. The standard **tail** -n \$LINES filename is correct.

See also Example 15-5, Example 15-38 and Example 29-6.

grep

A multi-purpose file search tool that uses <u>Regular Expressions</u>. It was originally a command/filter in the venerable **ed** line editor: **g/re/p** -- global - regular expression - print.

```
grep pattern[file...]
```

Search the target file(s) for occurrences of pattern, where pattern may be literal text or a Regular Expression.

```
bash$ grep '[rst]ystem.$' osinfo.txt
The GPL governs the distribution of the Linux operating system.
```

If no target file(s) specified, grep works as a filter on stdout, as in a pipe.

```
bash$ ps ax | grep clock
765 tty1 S 0:00 xclock
901 pts/1 S 0:00 grep clock
```

The -i option causes a case-insensitive search.

The -w option matches only whole words.

The -1 option lists only the files in which matches were found, but not the matching lines.

The -r (recursive) option searches files in the current working directory and all subdirectories below it.

The -n option lists the matching lines, together with line numbers.

```
bash$ grep -n Linux osinfo.txt
2:This is a file containing information about Linux.
6:The GPL governs the distribution of the Linux operating system.
```

The -v (or --invert-match) option filters out matches.

```
1 grep pattern1 *.txt | grep -v pattern2
2
3 # Matches all lines in "*.txt" files containing "pattern1",
4 # but ***not*** "pattern2".
```

The -c (-count) option gives a numerical count of matches, rather than actually listing the matches.

```
1 grep -c txt *.sgml # (number of occurrences of "txt" in "*.sgml" files)
2
3
4 # grep -cz .
5 # ^ dot
```

```
6 # means count (-c) zero-separated (-z) items matching "."
7 # that is, non-empty ones (containing at least 1 character).
8 #
9 printf 'a b\nc d\n\n\n\n\000\n\000e\000\000\nf' | grep -cz . # 3
10 printf 'a b\nc d\n\n\n\n\n\000\n\000e\000\000\nf' | grep -cz '$' # 5
11 printf 'a b\nc d\n\n\n\n\n\000\n\000e\000\000\nf' | grep -cz '^' # 5
12 #
13 printf 'a b\nc d\n\n\n\n\n\000\n\000e\000\000\nf' | grep -c '$' # 9
14 # By default, newline chars (\n) separate items to match.
15
16 # Note that the -z option is GNU "grep" specific.
17
18
19 # Thanks, S.C.
```

The --color (or --colour) option marks the matching string in color (on the console or in an *xterm* window). Since *grep* prints out each entire line containing the matching pattern, this lets you see exactly *what* is being matched. See also the $-\circ$ option, which shows only the matching portion of the line(s).

Example 15-16. Printing out the *From* lines in stored e-mail messages

```
1 #!/bin/bash
 2 # from.sh
 4 # Emulates the useful "from" utility in Solaris, BSD, etc.
 5 # Echoes the "From" header line in all messages
 6 #+ in your e-mail directory.
 8
9 MAILDIR=~/mail/*
                               # No quoting of variable. Why?
10 GREP_OPTS="-H -A 5 --color" # Show file, plus extra context lines
                             #+ and display "From" in color.
11
12 TARGETSTR="^From"
                                # "From" at beginning of line.
13
14 for file in $MAILDIR
                               # No quoting of variable.
16 grep $GREP_OPTS "$TARGETSTR" "$file"
17 # ^^^^^^
                               # Again, do not quote this variable.
18 echo
19 done
20
21 exit $?
23 # Might wish to pipe the output of this script to 'more' or
24 #+ redirect it to a file . . .
```

When invoked with more than one target file given, **grep** specifies which file contains matches.

```
bash$ grep Linux osinfo.txt misc.txt
  osinfo.txt:This is a file containing information about Linux.
  osinfo.txt:The GPL governs the distribution of the Linux operating system.
  misc.txt:The Linux operating system is steadily gaining in popularity.
```

To force **grep** to show the filename when searching only one target file, simply give /dev/null as the second file.

```
bash$ grep Linux osinfo.txt /dev/null
  osinfo.txt:This is a file containing information about Linux.
  osinfo.txt:The GPL governs the distribution of the Linux operating system.
```

If there is a successful match, **grep** returns an <u>exit status</u> of 0, which makes it useful in a condition test in a script, especially in combination with the –q option to suppress output.

<u>Example 29-6</u> demonstrates how to use **grep** to search for a word pattern in a system logfile.

Example 15-17. Emulating grep in a script

```
1 #!/bin/bash
  2 # grp.sh: Very crude reimplementation of 'grep'.
  4 E BADARGS=65
 6 if [ -z "$1" ] # Check for argument to script.
    echo "Usage: `basename $0` pattern"
 9 exit $E_BADARGS
 10 fi
 11
 12 echo
 13
 14 for file in * # Traverse all files in $PWD.
15 do
16 output=$(sed -n /"$1"/p $file) # Command substitution.
17
 18 if [!-z "$output"] # What happens if "$output" is not quoted?
 19 then
20 echo -n "$file: "
21 echo $output
      echo $output
 22 fi
            # sed -ne \frac{1}{s}^{\frac{1}{s}} | $\file\}: |p\| is equivalent to above.
 23
 24 echo
 25 done
 26
 27 echo
 28
 29 exit 0
 30
 31 # Exercises:
 33 # 1) Add newlines to output, if more than one match in any given file.
34 # 2) Add features.
```

How can **grep** search for two (or more) separate patterns? What if you want **grep** to display all lines in a file or files that contain both "pattern1" *and* "pattern2"?

One method is to <u>pipe</u> the result of **grep pattern1** to **grep pattern2**.

For example, given the following file:

```
1 # Filename: tstfile
3 This is a sample file.
4 This is an ordinary text file.
5 This file does not contain any unusual text.
6 This file is not unusual.
7 Here is some text.
```

Now, let's search this file for lines containing both "file" and "text" . . .

```
bash$ grep file tstfile
 # Filename: tstfile
This is a sample file.
This is an ordinary text file.
This file does not contain any unusual text.
 This file is not unusual.
bash$ grep file tstfile | grep text
This is an ordinary text file.
This file does not contain any unusual text.
```

egrep -- extended grep -- is the same as grep -E. This uses a somewhat different, extended set of Regular Expressions, which can make the search a bit more flexible. It also allows the boolean | (or) operator.

```
bash $ egrep 'matches|Matches' file.txt
Line 1 matches.
Line 3 Matches.
Line 4 contains matches, but also Matches
```

fgrep -- fast grep -- is the same as **grep** -F. It does a literal string search (no Regular Expressions), which usually speeds things up a bit.

On some Linux distros, **egrep** and **fgrep** are symbolic links to, or aliases for **grep**, but invoked with the $-\mathbb{E}$ and $-\mathbb{F}$ options, respectively.

Example 15-18. Looking up definitions in Webster's 1913 Dictionary

```
1 #!/bin/bash
 2 # dict-lookup.sh
 4 # This script looks up definitions in the 1913 Webster's Dictionary.
 5 # This Public Domain dictionary is available for download
 6 #+ from various sites, including
 7 #+ Project Gutenberg (http://www.gutenberg.org/etext/247).
 8 #
 9 # Convert it from DOS to UNIX format (only LF at end of line)
10 #+ before using it with this script.
11 # Store the file in plain, uncompressed ASCII.
12 # Set DEFAULT_DICTFILE variable below to path/filename.
13
14
15 E_BADARGS=65

71 exit 0
72.
73 # Exercises:
74 # -----
75 # 1) Modify the script to accept any type of alphabetic input
76 # + (uppercase, lowercase, mixed case), and convert it
77 #
     + to an acceptable format for processing.
78 #
79 \# 2) Convert the script to a GUI application,
     + using something like 'gdialog' or 'zenity' . . .
      The script will then no longer take its argument(s)
81 #
     + from the command line.
82 #
83 #
84 # 3) Modify the script to parse one of the other available
85 # + Public Domain Dictionaries, such as the U.S. Census Bureau Gazetteer.
```

agrep (*approximate grep*) extends the capabilities of **grep** to approximate matching. The search string may differ by a specified number of characters from the resulting matches. This utility is not part of the core Linux distribution.

To search compressed files, use **zgrep**, **zegrep**, or **zfgrep**. These also work on non-compressed files, though slower than plain **grep**, **egrep**, **fgrep**. They are handy for searching through a mixed set of files, some compressed, some not.

To search <u>bzipped</u> files, use **bzgrep**.

look

The command **look** works like **grep**, but does a lookup on a "dictionary," a sorted word list. By default, **look** searches for a match in /usr/dict/words, but a different dictionary file may be specified.

Example 15-19. Checking words in a list for validity

```
1 #!/bin/bash
 2 # lookup: Does a dictionary lookup on each word in a data file.
 4 file=words.data # Data file from which to read words to test.
 8 while [ "$word" != end ] # Last word in data file.
9 do # ^^^
10 read word # From data file, because of redirection at end of loop.
   look $word > /dev/null # Don't want to display lines in dictionary file.
11
12 lookup=$? # Exit status of 'look' command.
1.3
14 if [ "$lookup" -eq 0 ]
15 then
16 echo "\"$word\" is valid."
17 else
18 echo "\"$word\" is invalid."
19 fi
20
21 done <"$file" # Redirects stdin to $file, so "reads" come from there.
22
23 echo
2.4
25 exit 0
27 # -----
28 # Code below line will not execute because of "exit" command above.
30
31 # Stephane Chazelas proposes the following, more concise alternative:
32
33 while read word && [[ $word != end ]]
34 do if look "$word" > /dev/null
35 then echo "\"$word\" is valid."
36 else echo "\"$word\" is invalid."
37 fi
38 done <"$file"
40 exit 0
```

Scripting languages especially suited for parsing text files and command output. May be embedded singly or in combination in pipes and shell scripts.

sed

Non-interactive "stream editor", permits using many **ex** commands in <u>batch</u> mode. It finds many uses in shell scripts.

<u>awk</u>

Programmable file extractor and formatter, good for manipulating and/or extracting fields (columns) in structured text files. Its syntax is similar to C.

wc

wc gives a "word count" on a file or I/O stream:

```
bash $ wc /usr/share/doc/sed-4.1.2/README

13 70 447 README

[13 lines 70 words 447 characters]
```

wc -w gives only the word count.

wc -1 gives only the line count.

wc -c gives only the byte count.

wc -m gives only the character count.

wc -L gives only the length of the longest line.

Using wc to count how many .txt files are in current working directory:

```
1 $ ls *.txt | wc -l
2 # Will work as long as none of the "*.txt" files
3 #+ have a linefeed embedded in their name.
4
5 # Alternative ways of doing this are:
6 # find . -maxdepth 1 -name \*.txt -print0 | grep -cz .
7 # (shopt -s nullglob; set -- *.txt; echo $#)
8
9 # Thanks, S.C.
```

Using wc to total up the size of all the files whose names begin with letters in the range d - h

```
bash$ wc [d-h]* | grep total | awk '{print $3}'
71832
```

Using wc to count the instances of the word "Linux" in the main source file for this book.

```
bash$ grep Linux abs-book.sgml | wc -l 50
```

See also Example 15-38 and Example 19-8.

Certain commands include some of the functionality of wc as options.

```
1 ... | grep foo | wc -l
2 # This frequently used construct can be more concisely rendered.
3
4 ... | grep -c foo
5 # Just use the "-c" (or "--count") option of grep.
6
7 # Thanks, S.C.
```

tr

character translation filter.

Must use quoting and/or brackets, as appropriate. Quotes prevent the shell from reinterpreting the special characters in **tr** command sequences. Brackets should be quoted to prevent expansion by the shell.

Either tr "A-Z" "*" <filename or tr A-Z * <filename changes all the uppercase letters in filename to asterisks (writes to stdout). On some systems this may not work, but tr A-Z '[**]' will.

The -d option deletes a range of characters.

The --squeeze-repeats (or -s) option deletes all but the first instance of a string of consecutive characters. This option is useful for removing excess whitespace.

```
bash$ echo "XXXXX" | tr --squeeze-repeats 'X'
```

The -c "complement" option *inverts* the character set to match. With this option, **tr** acts only upon those characters *not* matching the specified set.

```
bash$ echo "acfdeb123" | tr -c b-d + +c+d+b++++
```

Note that **tr** recognizes <u>POSIX character classes</u>. [1]

```
bash$ echo "abcd2ef1" | tr '[:alpha:]' -
---2-1
```

Example 15-20. toupper: Transforms a file to all uppercase.

```
1 #!/bin/bash
 2 # Changes a file to all uppercase.
 4 E_BADARGS=65
 6 if [ -z "$1" ] # Standard check for command line arg.
 8 echo "Usage: `basename $0` filename"
9 exit $E_BADARGS
10 fi
11
12 tr a-z A-Z <"$1"
14 # Same effect as above, but using POSIX character set notation:
15 # tr '[:lower:]' '[:upper:]' <"$1"
16 # Thanks, S.C.
17
18 exit 0
19
20 # Exercise:
21 # Rewrite this script to give the option of changing a file
22 #+ to *either* upper or lowercase.
```

Example 15-21. lowercase: Changes all filenames in working directory to lowercase.

```
1 #!/bin/bash
 2 #
 3 # Changes every filename in working directory to all lowercase.
 5 # Inspired by a script of John Dubois,
  6 #+ which was translated into Bash by Chet Ramey,
 7 #+ and considerably simplified by the author of the ABS Guide.
 9
 10 for filename in *
                                   # Traverse all files in directory.
 11 do
    fname=`basename $filename`
     n=`echo $fname | tr A-Z a-z` # Change name to lowercase.
 13
     if [ "$fname" != "$n" ]  # Rename only files not already lowercase.
 14
    then
 15
 16
       mv $fname $n
    fi
 17
 18 done
 19
 20 exit $?
 21
 2.2.
 23 # Code below this line will not execute because of "exit".
 24 #-----#
 25 # To run it, delete script above line.
 27 # The above script will not work on filenames containing blanks or newlines.
 28 # Stephane Chazelas therefore suggests the following alternative:
 29
 30
                      # Not necessary to use basename,
 31 for filename in *
                       # since "*" won't return any file containing "/".
 33 do n=`echo "$filename/" | tr '[:upper:]' '[:lower:]'`
 34 #
                                POSIX char set notation.
 35 #
                       Slash added so that trailing newlines are not
 36 #
                       removed by command substitution.
 37  # Variable substitution:
     n=${n%/} # Removes trailing slash, added above, from filename.
    [[ $filename == $n ]] || mv "$filename" "$n"
 39
 40
                     # Checks if filename already lowercase.
 41 done
42
43 exit $?
```

Example 15-22. du: DOS to UNIX text file conversion.

```
1 #!/bin/bash
2 # Du.sh: DOS to UNIX text file converter.
3
4 E_WRONGARGS=65
5
6 if [ -z "$1" ]
7 then
8 echo "Usage: `basename $0` filename-to-convert"
9 exit $E_WRONGARGS
10 fi
11
12 NEWFILENAME=$1.unx
13
14 CR='\015' # Carriage return.
```

```
15
              # 015 is octal ASCII code for CR.
16
              # Lines in a DOS text file end in CR-LF.
17
              # Lines in a UNIX text file end in LF only.
18
19 tr -d $CR < $1 > $NEWFILENAME
20 # Delete CR's and write to new file.
22 echo "Original DOS text file is \"$1\"."
23 echo "Converted UNIX text file is \"$NEWFILENAME\"."
25 exit 0
2.6
27 # Exercise:
28 # -----
29 # Change the above script to convert from UNIX to DOS.
```

Example 15-23. rot13: ultra-weak encryption.

```
1 #!/bin/bash
2 # rot13.sh: Classic rot13 algorithm,
3 # encryption that might fool a 3-year old.
4
5 # Usage: ./rot13.sh filename
6 # or ./rot13.sh <filename
7 # or ./rot13.sh and supply keyboard input (stdin)
8
9 cat "$@" | tr 'a-zA-Z' 'n-za-mN-ZA-M' # "a" goes to "n", "b" to "o", etc.
10 # The 'cat "$@"' construction
11 #+ permits getting input either from stdin or from files.
12
13 exit 0</pre>
```

Example 15-24. Generating "Crypto-Quote" Puzzles

```
1 #!/bin/bash
 2 # crypto-quote.sh: Encrypt quotes
 4 # Will encrypt famous quotes in a simple monoalphabetic substitution.
 5 # The result is similar to the "Crypto Quote" puzzles
 6 #+ seen in the Op Ed pages of the Sunday paper.
7
9 key=ETAOINSHRDLUBCFGJMQPVWZYXK
10 # The "key" is nothing more than a scrambled alphabet.
11 # Changing the "key" changes the encryption.
12
13 # The 'cat "$0"' construction gets input either from stdin or from files.
14 # If using stdin, terminate input with a Control-D.
15 # Otherwise, specify filename as command-line parameter.
17 cat "$@" | tr "a-z" "A-Z" | tr "A-Z" "$key"
       | to uppercase | encrypt
19 # Will work on lowercase, uppercase, or mixed-case quotes.
20 # Passes non-alphabetic characters through unchanged.
2.1
22
23 # Try this script with something like:
24 # "Nothing so needs reforming as other people's habits."
25 # --Mark Twain
```

```
26 #
27 # Output is:
28 # "CFPHRCS QF CIIOQ MINFMBRCS EQ FPHIM GIFGUI'Q HETRPQ."
29 # --BEML PZERC
31 # To reverse the encryption:
32 # cat "$@" | tr "$key" "A-Z"
33
34
35 # This simple-minded cipher can be broken by an average 12-year old
36 #+ using only pencil and paper.
37
38 exit 0
39
40 # Exercise:
41 #
42 # Modify the script so that it will either encrypt or decrypt,
43 #+ depending on command-line argument(s).
```

tr variants

The tr utility has two historic variants. The BSD version does not use brackets (tr a-z A-Z), but the SysV one does (tr '[a-z]' '[A-Z]'). The GNU version of tr resembles the BSD one.

fold

A filter that wraps lines of input to a specified width. This is especially useful with the -s option, which breaks lines at word spaces (see <u>Example 15-25</u> and <u>Example A-1</u>).

fmt

Simple-minded file formatter, used as a filter in a pipe to "wrap" long lines of text output.

Example 15-25. Formatted file listing.

```
1 #!/bin/bash
2
3 WIDTH=40  # 40 columns wide.
4
5 b=`ls /usr/local/bin`  # Get a file listing...
6
7 echo $b | fmt -w $WIDTH
8
9 # Could also have been done by
10 # echo $b | fold - -s -w $WIDTH
11
12 exit 0
```

See also Example 15-5.

A powerful alternative to **fmt** is Kamil Toman's **par** utility, available from http://www.cs.berkeley.edu/~amc/Par/.

col

This deceptively named filter removes reverse line feeds from an input stream. It also attempts to replace whitespace with equivalent tabs. The chief use of **col** is in filtering the output from certain text processing utilities, such as **groff** and **tbl**.

column

Column formatter. This filter transforms list-type text output into a "pretty-printed" table by inserting tabs at appropriate places.

Example 15-26. Using column to format a directory listing

```
1 #!/bin/bash
 2 # This is a slight modification of the example file in the "column" man page.
 5 (printf "PERMISSIONS LINKS OWNER GROUP SIZE MONTH DAY HH:MM PROG-NAME\n" \
 6 ; ls -1 | sed 1d) | column -t
 8 # The "sed 1d" in the pipe deletes the first line of output,
 9 #+ which would be "total N",
10 #+ where "N" is the total number of files found by "ls -l".
11
12 # The -t option to "column" pretty-prints a table.
14 exit 0
```

colrm

Column removal filter. This removes columns (characters) from a file and writes the file, lacking the range of specified columns, back to stdout. colrm 2 4 <filename removes the second through fourth characters from each line of the text file filename.

1 If the file contains tabs or nonprintable characters, this may cause unpredictable behavior. In such cases, consider using expand and unexpand in a pipe preceding colrm.

nl

Line numbering filter: nl filename lists filename to stdout, but inserts consecutive numbers at the beginning of each non-blank line. If filename omitted, operates on stdin.

The output of **nl** is very similar to **cat** -**b**, since, by default **nl** does not list blank lines.

Example 15-27. *nl*: A self-numbering script.

```
1 #!/bin/bash
 2 # line-number.sh
 4 # This script echoes itself twice to stdout with its lines numbered.
 6 # 'nl' sees this as line 4 since it does not number blank lines.
 7 \# 'cat -n' sees the above line as number 6.
 9 nl `basename $0`
10
11 echo; echo # Now, let's try it with 'cat -n'
12
13 cat -n `basename $0`
14 # The difference is that 'cat -n' numbers the blank lines.
15 # Note that 'nl -ba' will also do so.
17 exit 0
18 # ----
```

pr

Print formatting filter. This will paginate files (or stdout) into sections suitable for hard copy printing or viewing on screen. Various options permit row and column manipulation, joining lines, setting margins, numbering lines, adding page headers, and merging files, among other things. The pr command combines much of the functionality of nl, paste, fold, column, and expand.

pr -o 5 --width=65 fileZZZ | more gives a nice paginated listing to screen of fileZZZ with margins set at 5 and 65.

A particularly useful option is -d, forcing double-spacing (same effect as **sed -G**).

gettext

The GNU **gettext** package is a set of utilities for <u>localizing</u> and translating the text output of programs into foreign languages. While originally intended for C programs, it now supports quite a number of programming and scripting languages.

The **gettext** *program* works on shell scripts. See the *info* page.

msgfmt

A program for generating binary message catalogs. It is used for <u>localization</u>.

iconv

A utility for converting file(s) to a different encoding (character set). Its chief use is for <u>localization</u>.

```
1 # Convert a string from UTF-8 to UTF-16 and print to the BookList
2 function write_utf8_string {
3    STRING=$1
4    BOOKLIST=$2
5    echo -n "$STRING" | iconv -f UTF8 -t UTF16 | \
6    cut -b 3- | tr -d \\n >> "$BOOKLIST"
7 }
8
9 # From Peter Knowles' "booklistgen.sh" script
10 #+ for converting files to Sony Librie/PRS-50X format.
11 # (http://booklistgensh.peterknowles.com)
```

recode

Consider this a fancier version of **iconv**, above. This very versatile utility for converting a file to a different encoding scheme. Note that **recode>** is not part of the standard Linux installation.

TeX, gs

TeX and **Postscript** are text markup languages used for preparing copy for printing or formatted video display.

TeX is Donald Knuth's elaborate typsetting system. It is often convenient to write a shell script encapsulating all the options and arguments passed to one of these markup languages.

Ghostscript (gs) is a GPL-ed Postscript interpreter.

texexec

Utility for processing *TeX* and *pdf* files. Found in /usr/bin on many Linux distros, it is actually a shell wrapper that calls <u>Perl</u> to invoke *Tex*.

```
1 texexec --pdfarrange --result=Concatenated.pdf *pdf
2
3 # Concatenates all the pdf files in the current working directory
4 #+ into the merged file, Concatenated.pdf . . .
5 # (The --pdfarrange option repaginates a pdf file. See also --pdfcombine.)
6 # The above command line could be parameterized and put into a shell script.
```

enscript

Utility for converting plain text file to PostScript

For example, **enscript filename.txt -p filename.ps** produces the PostScript output file filename.ps.

groff, tbl, eqn

Yet another text markup and display formatting language is **groff**. This is the enhanced GNU version of the venerable UNIX **roff/troff** display and typesetting package. <u>Manpages</u> use **groff**.

The **tbl** table processing utility is considered part of **groff**, as its function is to convert table markup into **groff** commands.

The **eqn** equation processing utility is likewise part of **groff**, and its function is to convert equation markup into **groff** commands.

Example 15-28. manview: Viewing formatted manpages

```
1 #!/bin/bash
 2 # manview.sh: Formats the source of a man page for viewing.
 4 # This script is useful when writing man page source.
 5 # It lets you look at the intermediate results on the fly
 6 #+ while working on it.
 8 E_WRONGARGS=65
10 if [ -z "$1" ]
11 then
12 echo "Usage: `basename $0` filename"
13 exit $E_WRONGARGS
14 fi
1.5
17 groff -Tascii -man $1 | less
18 # From the man page for groff.
21 # If the man page includes tables and/or equations,
22 #+ then the above code will barf.
23 # The following line can handle such cases.
25 #
     gtbl < "$1" | geqn -Tlatin1 | groff -Tlatin1 -mtty-char -man
26 #
27 # Thanks, S.C.
29 exit 0
```

lex, yacc

The **lex** lexical analyzer produces programs for pattern matching. This has been replaced by the nonproprietary **flex** on Linux systems.

The **yacc** utility creates a parser based on a set of specifications. This has been replaced by the nonproprietary **bison** on Linux systems.

Notes

This is only true of the GNU version of **tr**, not the generic version often found on commercial UNIX systems.

Prev Chapter 15. External Filters, Programs and Commands Next

15.5. File and Archiving Commands

Archiving

tar

The standard UNIX archiving utility. [1] Originally a *Tape ARchiving* program, it has developed into a general purpose package that can handle all manner of archiving with all types of destination devices, ranging from tape drives to regular files to even stdout (see Example 3-4). GNU tar has been patched to accept various compression filters, for example: tar czvf archive_name.tar.gz *, which recursively archives and gzips all files in a directory tree except dotfiles in the current working directory (<u>\$PWD</u>). [2]

Some useful **tar** options:

- 1. −c create (a new archive)
- 2. -x extract (files from existing archive)
- 3. --delete delete (files from existing archive)
 - 1 This option will not work on magnetic tape devices.
- 4. -r append (files to existing archive)
- 5. –A append (*tar* files to existing archive)
- 6. -t list (contents of existing archive)
- 7. -u update archive
- 8. -d compare archive with specified filesystem
- 9. --after-date only process files with a date stamp after specified date
- 10. -z gzip the archive

(compress or uncompress, depending on whether combined with the -c or -x) option

11. − ¬ bzip2 the archive

1 It may be difficult to recover data from a corrupted gzipped tar archive. When archiving important files, make multiple backups.

shar

Shell archiving utility. The files in a shell archive are concatenated without compression, and the resultant archive is essentially a shell script, complete with #!/bin/sh header, and containing all the necessary unarchiving commands. Shar archives still show up in Usenet newsgroups, but otherwise shar has been pretty well replaced by tar/gzip. The unshar command unpacks shar archives.

ar

Creation and manipulation utility for archives, mainly used for binary object file libraries.

rpm

The Red Hat Package Manager, or rpm utility provides a wrapper for source or binary archives. It includes commands for installing and checking the integrity of packages, among other things.

A simple **rpm** -i package name.rpm usually suffices to install a package, though there are many more options available.

rpm -qf identifies which package a file originates from.

```
bash$ rpm -qf /bin/ls
 coreutils-5.2.1-31
```

rpm -qa gives a complete list of all installed *rpm* packages on a given system. An rpm -qa package_name lists only the package(s) corresponding to

package_name.

```
bash$ rpm -qa
redhat-logos-1.1.3-1
glibc-2.2.4-13
cracklib-2.7-12
dosfstools-2.7-1
gdbm-1.8.0-10
ksymoops-2.4.1-1
mktemp-1.5-11
perl-5.6.0-17
reiserfs-utils-3.x.0j-2
bash$ rpm -qa docbook-utils
docbook-utils-0.6.9-2
bash$ rpm -qa docbook | grep docbook
docbook-dtd31-sqml-1.0-10
docbook-style-dsssl-1.64-3
docbook-dtd30-sqml-1.0-10
docbook-dtd40-sgml-1.0-11
docbook-utils-pdf-0.6.9-2
docbook-dtd41-sqml-1.0-10
docbook-utils-0.6.9-2
```

cpio

This specialized archiving copy command (**copy i**nput and **o**utput) is rarely seen any more, having been supplanted by **tar/gzip**. It still has its uses, such as moving a directory tree. With an appropriate block size (for copying) specified, it can be appreciably faster than **tar**.

Example 15-29. Using cpio to move a directory tree

```
1 #!/bin/bash
 3 # Copying a directory tree using cpio.
 5 # Advantages of using 'cpio':
 6 # Speed of copying. It's faster than 'tar' with pipes.
 7 # Well suited for copying special files (named pipes, etc.)
 8 #+ that 'cp' may choke on.
10 ARGS=2
11 E_BADARGS=65
12
13 if [ $# -ne "$ARGS" ]
15 echo "Usage: `basename $0` source destination"
16 exit $E BADARGS
17 fi
18
19 source="$1"
20 destination="$2"
2.1
23 find "$source" -depth | cpio -admvp "$destination"
                ^ ^ ^ ^ ^
                             ^ ^ ^ ^ ^
25 # Read the 'find' and 'cpio' info pages to decipher these options.
26 # The above works only relative to $PWD (current directory) . . .
27 #+ full pathnames are specified.
```

```
29
30
31 # Exercise:
32 # -----
34 # Add code to check the exit status ($?) of the 'find | cpio' pipe
35 #+ and output appropriate error messages if anything went wrong.
36
37 exit $?
```

rpm2cpio

This command extracts a **cpio** archive from an <u>rpm</u> one.

Example 15-30. Unpacking an rpm archive

```
1 #!/bin/bash
 2 # de-rpm.sh: Unpack an 'rpm' archive
 4 : ${1?"Usage: `basename $0` target-file"}
 5 # Must specify 'rpm' archive name as an argument.
                                         # Tempfile with "unique" name.
 8 TEMPFILE=$$.cpio
 9
                                         # $$ is process ID of script.
10
11 rpm2cpio < $1 > $TEMPFILE
                                         # Converts rpm archive into
                                         #+ cpio archive.
13 cpio --make-directories -F $TEMPFILE -i # Unpacks cpio archive.
14 rm -f $TEMPFILE
                                        # Deletes cpio archive.
15
16 exit 0
17
18 # Exercise:
19 # Add check for whether 1) "target-file" exists and
20 #+
               it is an rpm archive.
                         Parse output of 'file' command.
21 # Hint:
```

Compression

gzip

The standard GNU/UNIX compression utility, replacing the inferior and proprietary compress. The corresponding decompression command is gunzip, which is the equivalent of gzip -d.

The **zcat** filter decompresses a gzipped file to stdout, as possible input to a pipe or redirection. This is, in effect, a cat command that works on compressed files (including files processed with the older compress utility). The zcat command is equivalent to gzip -dc.

1 On some commercial UNIX systems, zcat is a synonym for uncompress -c, and will not work on gzipped files.

See also Example 7-7.

bzip2

An alternate compression utility, usually more efficient (but slower) than gzip, especially on large

files. The corresponding decompression command is **bunzip2**.

Rewer versions of tar have been patched with bzip2 support.

compress, uncompress

This is an older, proprietary compression utility found in commercial UNIX distributions. The more efficient gzip has largely replaced it. Linux distributions generally include a compress workalike for compatibility, although **gunzip** can unarchive files treated with **compress**.

The **znew** command transforms *compressed* files into *gzipped* ones.

sq

Yet another compression (squeeze) utility, a filter that works only on sorted ASCII word lists. It uses the standard invocation syntax for a filter, sq < input-file > output-file. Fast, but not nearly as efficient as gzip. The corresponding uncompression filter is unsq, invoked like sq.

The output of sq may be piped to gzip for further compression.

zip, unzip

Cross-platform file archiving and compression utility compatible with DOS pkzip.exe. "Zipped" archives seem to be a more common medium of file exchange on the Internet than "tarballs."

unarc, unarj, unrar

These Linux utilities permit unpacking archives compressed with the DOS arc.exe, arj.exe, and rar.exe programs.

File Information

file

A utility for identifying file types. The command **file file-name** will return a file specification for file-name, such as ascii text or data. It references the magic numbers found in /usr/share/magic, /etc/magic, or /usr/lib/magic, depending on the Linux/UNIX distribution.

The -f option causes **file** to run in <u>batch</u> mode, to read from a designated file a list of filenames to analyze. The -z option, when used on a compressed target file, forces an attempt to analyze the uncompressed file type.

```
bash$ file test.tar.gz
test.tar.gz: gzip compressed data, deflated,
last modified: Sun Sep 16 13:34:51 2001, os: Unix
bash file -z test.tar.gz
 test.tar.gz: GNU tar archive (gzip compressed data, deflated,
 last modified: Sun Sep 16 13:34:51 2001, os: Unix)
```

```
1 # Find sh and Bash scripts in a given directory:
 3 DIRECTORY=/usr/local/bin
 4 KEYWORD=Bourne
 5 # Bourne and Bourne-Again shell scripts
 7 file $DIRECTORY/* | fgrep $KEYWORD
 9 # Output:
10
11 # /usr/local/bin/burn-cd: Bourne-Again shell script text executable
12 # /usr/local/bin/burnit: Bourne-Again shell script text executable
13 # /usr/local/bin/cassette.sh: Bourne shell script text executable
```

```
14 # /usr/local/bin/cop
15 # . . .
```

Example 15-31. Stripping comments from C program files

```
1 #!/bin/bash
 2 # strip-comment.sh: Strips out the comments (/* COMMENT */) in a C program.
4 E_NOARGS=0
5 E_ARGERROR=66
6 E_WRONG_FILE_TYPE=67
8 if [ $# -eq "$E_NOARGS" ]
10 echo "Usage: `basename $0` C-program-file" >&2 # Error message to stderr.
11 exit $E_ARGERROR
12 fi
13
14 # Test for correct file type.
15 type=`file $1 | awk '{ print $2, $3, $4, $5 }'`
16 # "file $1" echoes file type . . .
17 # Then awk removes the first field, the filename . . .
18 # Then the result is fed into the variable "type."
19 correct_type="ASCII C program text"
20
21 if [ "$type" != "$correct_type" ]
22 then
23 echo
24 echo "This script works on C program files only."
25 echo
26 exit $E_WRONG_FILE_TYPE
27 fi
28
29
30 # Rather cryptic sed script:
31 #----
32 sed '
33 /^\/\*/d
34 /.*\*\/d
35 ' $1
36 #----
37 # Easy to understand if you take several hours to learn sed fundamentals.
39
40 # Need to add one more line to the sed script to deal with
41 #+ case where line of code has a comment following it on same line.
42 # This is left as a non-trivial exercise.
43
44 \# Also, the above code deletes non-comment lines with a "*/" . . .
45 #+ not a desirable result.
46
47 exit 0
48
49
51 # Code below this line will not execute because of 'exit 0' above.
53 # Stephane Chazelas suggests the following alternative:
54
55 usage() {
56 echo "Usage: `basename $0` C-program-file" >&2
57
    exit 1
58 }
59
```

```
60 WEIRD=`echo -n -e '\377'` # or WEIRD=$'\377'
61 [[ $# -eq 1 ]] || usage
62 case `file "$1"` in
63 *"C program text"*) sed -e "s%/\*%${WEIRD}%g;s%\*/%${WEIRD}%g" "$1" \
     | tr '\377\n' '\n\377' \
       | sed -ne 'p;n' \
6.5
      | tr -d '\n' | tr '\377' '\n';;
66
67 *) usage;;
68 esac
69
70 # This is still fooled by things like:
71 # printf("/*");
72 # or
73 \# /* /* buggy embedded comment */
74 #
75 # To handle all special cases (comments in strings, comments in string
76 #+ where there is a \", \ \\" ...),
77 #+ the only way is to write a C parser (using lex or yacc perhaps?).
78
79 exit 0
```

which

which command gives the full path to "command." This is useful for finding out whether a particular command or utility is installed on the system.

\$bash which rm

```
/usr/bin/rm
```

For an interesting use of this command, see Example 33-14.

whereis

Similar to **which**, above, **whereis command** gives the full path to "command," but also to its manpage.

\$bash whereis rm

```
rm: /bin/rm /usr/share/man/man1/rm.1.bz2
```

whatis

whatis command looks up "command" in the whatis database. This is useful for identifying system commands and important configuration files. Consider it a simplified man command.

\$bash whatis whatis

```
whatis (1) - search the whatis database for complete words
```

Example 15-32. Exploring /usr/X11R6/bin

```
1 #!/bin/bash
2
3 # What are all those mysterious binaries in /usr/X11R6/bin?
4
5 DIRECTORY="/usr/X11R6/bin"
6 # Try also "/bin", "/usr/bin", "/usr/local/bin", etc.
7
8 for file in $DIRECTORY/*
9 do
10 whatis `basename $file` # Echoes info about the binary.
11 done
12
```

```
13 exit 0
14
15 # You may wish to redirect output of this script, like so:
16 # ./what.sh >>whatis.db
17 # or view it a page at a time on stdout,
18 # ./what.sh | less
```

See also Example 10-3.

vdir

Show a detailed directory listing. The effect is similar to <u>ls -lb</u>.

This is one of the GNU fileutils.

locate, slocate

The **locate** command searches for files using a database stored for just that purpose. The **slocate** command is the secure version of **locate** (which may be aliased to **slocate**).

\$bash locate hickson

```
/usr/lib/xephem/catalogs/hickson.edb
```

readlink

Disclose the file that a symbolic link points to.

```
bash$ readlink /usr/bin/awk
../../bin/gawk
```

strings

Use the **strings** command to find printable strings in a binary or data file. It will list sequences of printable characters found in the target file. This might be handy for a quick 'n dirty examination of a core dump or for looking at an unknown graphic image file (**strings image-file** | **more** might show something like *JFIF*, which would identify the file as a *jpeg* graphic). In a script, you would probably parse the output of **strings** with grep or sed. See Example 10-7 and Example 10-9.

Example 15-33. An "improved" strings command

```
12 E_BADARGS=65
13 E_NOFILE=66
14
15 if [ $# -ne $ARGS ]
17 echo "Usage: `basename $0` filename"
18 exit $E_BADARGS
19 fi
20
21 if [ ! -f "$1" ]
                                        # Check if file exists.
23 echo "File \"$1\" does not exist."
24
      exit $E_NOFILE
25 fi
26 # ======
27
28
29 MINSTRLEN=3
                                        # Minimum string length.
30 WORDFILE=/usr/share/dict/linux.words # Dictionary file.
                                        # May specify a different
31
                                        #+ word list file
32
33
                                        #+ of one-word-per-line format.
34
35
36 wlist=`strings "$1" | tr A-Z a-z | tr '[:space:]' Z | \
37 tr -cs '[:alpha:]' Z | tr -s '\173-\377' Z | tr Z ' '`
39 # Translate output of 'strings' command with multiple passes of 'tr'.
40 # "tr A-Z a-z" converts to lowercase.
41 # "tr '[:space:]'" converts whitespace characters to Z's.
42 # "tr -cs '[:alpha:]' Z" converts non-alphabetic characters to Z's,
43 \#+ and squeezes multiple consecutive Z's.
44 \# "tr -s '\173-\377' Z" converts all characters past 'z' to Z's
45 #+ and squeezes multiple consecutive Z's,
46 #+ which gets rid of all the weird characters that the previous
47 #+ translation failed to deal with.
48 # Finally, "tr Z ' '" converts all those Z's to whitespace,
49 #+ which will be seen as word separators in the loop below.
51 #
52 # Note the technique of feeding the output of 'tr' back to itself,
53 #+ but with different arguments and/or options on each pass.
5.5
56
57 for word in $wlist
                                        # Important:
                                        # $wlist must not be quoted here.
59
                                        # "$wlist" does not work.
                                        # Why not?
60
61 do
62
63 strlen=${#word}
                                        # String length.
64 if [ "$strlen" -lt "$MINSTRLEN" ] # Skip over short strings.
65 then
     continue
66
   fi
67
68
69 grep -Fw $word "$WORDFILE"
                                       # Match whole words only.
     ^^^
                                        # "Fixed strings" and
70 #
71
                                        #+ "whole words" options.
72
73 done
74
75
76 exit $?
```

Comparison

diff, patch

diff: flexible file comparison utility. It compares the target files line-by-line sequentially. In some applications, such as comparing word dictionaries, it may be helpful to filter the files through <u>sort</u> and **uniq** before piping them to **diff**. **diff file-1 file-2** outputs the lines in the files that differ, with carets showing which file each particular line belongs to.

The --side-by-side option to **diff** outputs each compared file, line by line, in separate columns, with non-matching lines marked. The -c and -u options likewise make the output of the command easier to interpret.

There are available various fancy frontends for diff, such as sdiff, wdiff, xdiff, and mgdiff.

The **diff** command returns an exit status of 0 if the compared files are identical, and 1 if they differ. This permits use of **diff** in a test construct within a shell script (see below).

A common use for **diff** is generating difference files to be used with **patch** The -e option outputs files suitable for **ed** or **ex** scripts.

patch: flexible versioning utility. Given a difference file generated by **diff**, **patch** can upgrade a previous version of a package to a newer version. It is much more convenient to distribute a relatively small "diff" file than the entire body of a newly revised package. Kernel "patches" have become the preferred method of distributing the frequent releases of the Linux kernel.

```
1 patch -p1 <patch-file
2 # Takes all the changes listed in 'patch-file'
3 # and applies them to the files referenced therein.
4 # This upgrades to a newer version of the package.</pre>
```

Patching the kernel:

```
1 cd /usr/src
2 gzip -cd patchXX.gz | patch -p0
3 # Upgrading kernel source using 'patch'.
4 # From the Linux kernel docs "README",
5 # by anonymous author (Alan Cox?).
```

The **diff** command can also recursively compare directories (for the filenames present).

```
bash$ diff -r ~/notes1 ~/notes2
Only in /home/bozo/notes1: file02
Only in /home/bozo/notes1: file03
Only in /home/bozo/notes2: file04
```

Use **zdiff** to compare *gzipped* files.

Use diffstat to create a histogram (point-distribution graph) of output from diff.

diff3

An extended version of **diff** that compares three files at a time. This command returns an exit value of 0 upon successful execution, but unfortunately this gives no information about the results of the comparison.

```
bash$ diff3 file-1 file-2 file-3
 1:1c
  This is line 1 of "file-1".
  This is line 1 of "file-2".
  This is line 1 of "file-3"
```

sdiff

Compare and/or edit two files in order to merge them into an output file. Because of its interactive nature, this command would find little use in a script.

cmp

The **cmp** command is a simpler version of **diff**, above. Whereas **diff** reports the differences between two files, **cmp** merely shows at what point they differ.

Like diff, cmp returns an exit status of 0 if the compared files are identical, and 1 if they differ. This permits use in a test construct within a shell script.

Example 15-34. Using *cmp* to compare two files within a script.

```
1 #!/bin/bash
 3 ARGS=2 # Two args to script expected.
 4 E_BADARGS=65
 5 E_UNREADABLE=66
 7 if [ $# -ne "$ARGS" ]
    echo "Usage: `basename $0` file1 file2"
    exit $E_BADARGS
10
11 fi
12
13 if [[ ! -r "$1" || ! -r "$2" ]]
15 echo "Both files to be compared must exist and be readable."
16 exit $E_UNREADABLE
17 fi
19 cmp $1 $2 &> /dev/null # /dev/null buries the output of the "cmp" command.
20 # cmp -s $1 $2 has same result ("-s" silent flag to "cmp")
21 # Thank you Anders Gustavsson for pointing this out.
23 # Also works with 'diff', i.e., diff $1 $2 &> /dev/null
2.4
                          # Test exit status of "cmp" command.
25 if [ $? -eq 0 ]
26 then
   echo "File \"$1\" is identical to file \"$2\"."
28 else
   echo "File \"$1\" differs from file \"$2\"."
30 fi
32 exit 0
```

(i) Use **zcmp** on *gzipped* files.

comm

Versatile file comparison utility. The files must be sorted for this to be useful.

comm -options first-file second-file

comm file-1 file-2 outputs three columns:

```
♦ column 1 = lines unique to file-1
♦ column 2 = lines unique to file-2
\Diamond column 3 = lines common to both.
```

The options allow suppressing output of one or more columns.

```
♦ -1 suppresses column 1
♦ –2 suppresses column 2
♦ -3 suppresses column 3
\Diamond -12 suppresses both columns 1 and 2, etc.
```

This command is useful for comparing "dictionaries" or word lists -- sorted text files with one word per line.

Utilities

basename

Strips the path information from a file name, printing only the file name. The construction basename \$0 lets the script know its name, that is, the name it was invoked by. This can be used for "usage" messages if, for example a script is called with missing arguments:

```
1 echo "Usage: `basename $0` arg1 arg2 ... argn"
```

dirname

Strips the **basename** from a filename, printing only the path information.

basename and dirname can operate on any arbitrary string. The argument does not need to refer to an existing file, or even be a filename for that matter (see Example A-7).

Example 15-35. basename and dirname

```
1 #!/bin/bash
3 a=/home/bozo/daily-journal.txt
5 echo "Basename of /home/bozo/daily-journal.txt = `basename $a`"
 6 echo "Dirname of /home/bozo/daily-journal.txt = `dirname $a`"
7 echo
8 echo "My own home is `basename ~/`."
                                             # `basename ~` also works.
9 echo "The home of my home is `dirname ~/`." # `dirname ~` also works.
1.0
11 exit 0
```

split, csplit

These are utilities for splitting a file into smaller chunks. Their usual use is for splitting up large files in order to back them up on floppies or preparatory to e-mailing or uploading them.

The **csplit** command splits a file according to *context*, the split occurring where patterns are matched.

Example 15-36. A script that copies itself in sections

```
1 #!/bin/bash
2 # splitcopy.sh
```

```
4 # A script that splits itself into chunks,
 5 #+ then reassembles the chunks into an exact copy
 6 #+ of the original script.
 8 CHUNKSIZE=4 # Size of first chunk of split files.
9 OUTPREFIX=xx # csplit prefixes, by default,
10
                #+ files with "xx" ...
11
12 csplit "$0" "$CHUNKSIZE"
13
14 # Some comment lines for padding . . .
15 # Line 15
16 # Line 16
17 # Line 17
18 # Line 18
19 # Line 19
20 # Line 20
22 cat "$OUTPREFIX"* > "$0.copy" # Concatenate the chunks.
23 rm "$OUTPREFIX"*
                                # Get rid of the chunks.
2.4
25 exit $?
```

Encoding and Encryption

sum, cksum, md5sum, sha1sum

These are utilities for generating checksums. A *checksum* is a number mathematically calculated from the contents of a file, for the purpose of checking its integrity. A script might refer to a list of checksums for security purposes, such as ensuring that the contents of key system files have not been altered or corrupted. For security applications, use the **md5sum** (**m**essage **d**igest **5** check**sum**) command, or better yet, the newer **sha1sum** (Secure Hash Algorithm).

```
bash$ cksum /boot/vmlinuz
1670054224 804083 /boot/vmlinuz

bash$ echo -n "Top Secret" | cksum
3391003827 10

bash$ md5sum /boot/vmlinuz
0f43eccea8f09e0a0b2b5cf1dcf333ba /boot/vmlinuz

bash$ echo -n "Top Secret" | md5sum
8babc97a6f62a4649716f4df8d61728f -
```

The cksum command shows the size, in bytes, of its target, whether file or stdout.

The **md5sum** and **sha1sum** commands display a <u>dash</u> when they receive their input from stdout.

Example 15-37. Checking file integrity

```
1 #!/bin/bash
2 # file-integrity.sh: Checking whether files in a given directory
3 # have been tampered with.
4
5 E_DIR_NOMATCH=70
6 E_BAD_DBFILE=71
```

```
8 dbfile=File_record.md5
9 # Filename for storing records (database file).
10
11
12 set_up_database ()
13 {
14 echo ""$directory"" > "$dbfile"
15 # Write directory name to first line of file.
16 md5sum "$directory"/* >> "$dbfile"
17 # Append md5 checksums and filenames.
18 }
19
20 check_database ()
21 {
22 local n=0
23
   local filename
24
   local checksum
25
2.6
27 # This file check should be unnecessary,
   #+ but better safe than sorry.
28
29
30 if [!-r "$dbfile"]
31 then
32 echo "Unable to read checksum database file!"
33
     exit $E_BAD_DBFILE

51
       # md5sum writes records backwards,
52
       #+ checksum first, then filename.
53
       checksum[n]=$( md5sum "${filename[n]}" )
54
55
       if [ "${record[n]}" = "${checksum[n]}" ]
56
57
        then
58
         echo "${filename[n]} unchanged."
59
        elif [ "`basename ${filename[n]}`" != "$dbfile" ]
60
               # Skip over checksum database file,
61
62
               #+ as it will change with each invocation of script.
63
64
          # This unfortunately means that when running
65
          #+ this script on $PWD, tampering with the
          #+ checksum database file will not be detected.
66
          # Exercise: Fix this.
67
68
     then
69
           echo "${filename[n]} : CHECKSUM ERROR!"
70
          # File has been changed since last checked.
71
        fi
72
```

```
fi
 73
 74
 75
 76
 77
      let "n+=1"
 78 done <"$dbfile" # Read from checksum database file.
 79
80 }
81
82 # ========== #
83 # main ()
85 if [ -z "$1" ]
86 then
87 directory="$PWD"
                     # If not specified,
                        #+ use current working directory.
 88 else
89 directory="$1"
 90 fi
 91
                         # Clear screen.
92 clear
93 echo " Running file integrity check on $directory"
94 echo
95
96 # -----
97 if [ ! -r "$dbfile" ] # Need to create database file?
echo "Setting up database file, \""$directory"/"$dbfile"\"."; echo
100
      set_up_database
101 fi
102 # ---
103
104 check_database  # Do the actual work.
105
106 echo
107
108 # You may wish to redirect the stdout of this script to a file,
109 #+ especially if the directory checked has many files in it.
110
111 exit 0
112
113 # For a much more thorough file integrity check,
114 #+ consider the "Tripwire" package,
115 #+ http://sourceforge.net/projects/tripwire/.
116
```

Also see Example A-20, Example 33-14, and Example 9-11 for creative uses of the **md5sum** command.

There have been reports that the 128-bit **md5sum** can be cracked, so the more secure 160-bit **sha1sum** is a welcome new addition to the checksum toolkit.

```
bash$ md5sum testfile
e181e2c8720c60522c4c4c981108e367 testfile

bash$ sha1sum testfile
5d7425a9c08a66c3177f1e31286fa40986ffc996 testfile
```

Security consultants have demonstrated that even **sha1sum** can be compromised. Fortunately, newer Linux distros include longer bit-length **sha224sum**, **sha256sum**, **sha384sum**, and **sha512sum** commands.

Securely erase a file by overwriting it multiple times with random bit patterns before deleting it. This command has the same effect as Example 15-58, but does it in a more thorough and elegant manner.

This is one of the GNU fileutils.

1 Advanced forensic technology may still be able to recover the contents of a file, even after application of **shred**.

uuencode

This utility encodes binary files (images, sound files, compressed files, etc.) into ASCII characters, making them suitable for transmission in the body of an e-mail message or in a newsgroup posting. This is especially useful where MIME (multimedia) encoding is not available.

uudecode

This reverses the encoding, decoding *uuencoded* files back into the original binaries.

Example 15-38. Uudecoding encoded files

```
1 #!/bin/bash
 2 # Uudecodes all uuencoded files in current working directory.
                # Allow 35 lines for the header (very generous).
 4 lines=35
 6 for File in * # Test all the files in $PWD.
   search1=`head -n $lines $File | grep begin | wc -w`
   search2=`tail -n $lines $File | grep end | wc -w`
   # Uuencoded files have a "begin" near the beginning,
   #+ and an "end" near the end.
11
12 if [ "$search1" -gt 0 ]
13 then
14 if [ "$search2" -gt 0 ]
15
     then
     echo "uudecoding - $File -"
uudecode $File
16
17
18 fi
19 fi
20 done
21
22 # Note that running this script upon itself fools it
23 #+ into thinking it is a uuencoded file,
24 #+ because it contains both "begin" and "end".
25
26 # Exercise:
27 #
28 # Modify this script to check each file for a newsgroup header,
29 #+ and skip to next if not found.
31 exit 0
```

(i) The fold -s command may be useful (possibly in a pipe) to process long uudecoded text messages downloaded from Usenet newsgroups.

mimencode, mmencode

The **mimencode** and **mmencode** commands process multimedia-encoded e-mail attachments. Although mail user agents (such as pine or kmail) normally handle this automatically, these particular utilities permit manipulating such attachments manually from the command line or in batch processing mode by means of a shell script.

crypt

At one time, this was the standard UNIX file encryption utility. [3] Politically motivated government regulations prohibiting the export of encryption software resulted in the disappearance of crypt from much of the UNIX world, and it is still missing from most Linux distributions. Fortunately, programmers have come up with a number of decent alternatives to it, among them the author's very own <u>cruft</u> (see <u>Example A-4</u>).

Miscellaneous

mktemp

Create a *temporary file* [4] with a "unique" filename. When invoked from the command line without additional arguments, it creates a zero-length file in the /tmp directory.

```
bash$ mktemp / tmp/tmp.zzsvql3154
```

```
1 PREFIX=filename
 2 tempfile=`mktemp $PREFIX.XXXXXX`
                           ^^^^^ Need at least 6 placeholders
 4 #+
                                 in the filename template.
 5 # If no filename template supplied,
 6 #+ "tmp.XXXXXXXXX" is the default.
 8 echo "tempfile name = $tempfile"
 9 # tempfile name = filename.QA2ZpY
10 #
                     or something similar...
11
12 # Creates a file of that name in the current working directory
13 #+ with 600 file permissions.
14 # A "umask 177" is therefore unnecessary,
15 #+ but it's good programming practice anyhow.
```

make

Utility for building and compiling binary packages. This can also be used for any set of operations that is triggered by incremental changes in source files.

The make command checks a Makefile, a list of file dependencies and operations to be carried out.

The *make* utility is, in effect, a powerful scripting language similar in many ways to *Bash*, but with the capability of recognizing *dependencies*. For in-depth coverage of this useful tool set, see the <u>GNU</u> software documentation site.

install

Special purpose file copying command, similar to **cp**, but capable of setting permissions and attributes of the copied files. This command seems tailormade for installing software packages, and as such it shows up frequently in Makefiles (in the *make install*: section). It could likewise find use in installation scripts.

dos2unix

This utility, written by Benjamin Lin and collaborators, converts DOS-formatted text files (lines terminated by CR-LF) to UNIX format (lines terminated by LF only), and vice-versa.

ptx

The **ptx** [targetfile] command outputs a permuted index (cross-reference list) of the targetfile. This may be further filtered and formatted in a pipe, if necessary.

more, less

Pagers that display a text file or stream to stdout, one screenful at a time. These may be used to filter the output of stdout... or of a script.

An interesting application of **more** is to "test drive" a command sequence, to forestall potentially unpleasant consequences.

Notes

- [1] An archive, in the sense discussed here, is simply a set of related files stored in a single location.
- [2] A **tar czvf archive_name.tar.gz** * *will* include dotfiles in directories *below* the current working directory. This is an undocumented GNU **tar** "feature".
- [3] This is a symmetric block cipher, used to encrypt files on a single system or local network, as opposed to the "public key" cipher class, of which **pgp** is a well-known example.
- [4] Creates a temporary *directory* when invoked with the -d option.

15.6. Communications Commands

Certain of the following commands find use in <u>chasing spammers</u>, as well as in network data transfer and analysis.

Information and Statistics

host

Searches for information about an Internet host by name or IP address, using DNS.

```
bash$ host surfacemail.com surfacemail.com. has address 202.92.42.236
```

ipcalc

Displays IP information for a host. With the -h option, **ipcalc** does a reverse DNS lookup, finding the name of the host (server) from the IP address.

```
bash$ ipcalc -h 202.92.42.236
HOSTNAME=surfacemail.com
```

nslookup

Do an Internet "name server lookup" on a host by IP address. This is essentially equivalent to **ipcalc** $-\mathbf{h}$ or \mathbf{dig} $-\mathbf{x}$. The command may be run either interactively or noninteractively, i.e., from within a script.

The **nslookup** command has allegedly been "deprecated," but it is still useful.

```
bash$ nslookup -sil 66.97.104.180
nslookup kuhleersparnis.ch
Server: 135.116.137.2
Address: 135.116.137.2#53

Non-authoritative answer:
Name: kuhleersparnis.ch
```

dig

Domain Information Groper. Similar to **nslookup**, **dig** does an Internet "name server lookup" on a host. May be run either interactively or noninteractively, i.e., from within a script.

Some interesting options to **dig** are +time=N for setting a query timeout to N seconds, +nofail for continuing to query servers until a reply is received, and -x for doing a reverse address lookup.

Compare the output of dig -x with ipcalc -h and nslookup.

```
bash$ dig -x 81.9.6.2
;; Got answer:
;; ->>HEADER<<- opcode: QUERY, status: NXDOMAIN, id: 11649
;; flags: qr rd ra; QUERY: 1, ANSWER: 0, AUTHORITY: 1, ADDITIONAL: 0

Example 15-39. Finding out where to report a spammer

```
1 #!/bin/bash
 2 # spam-lookup.sh: Look up abuse contact to report a spammer.
 3 # Thanks, Michael Zick.
 5 # Check for command-line arg.
 6 ARGCOUNT=1
 7 E WRONGARGS=65
 8 if [ $# -ne "$ARGCOUNT" ]
 9 then
10 echo "Usage: `basename $0` domain-name"
11 exit $E_WRONGARGS
12 fi
13
15 dig +short $1.contacts.abuse.net -c in -t txt
16 # Also try:
17 # dig +nssearch $1
18 #
         Tries to find "authoritative name servers" and display SOA records.
19
20 # The following also works:
21 # whois -h whois.abuse.net $1
22 # ^^ ^^^^^^^^ Specify host.
23 # Can even lookup multiple spammers with this, i.e."
24 # whois -h whois.abuse.net $spamdomain1 $spamdomain2 . . .
        ^^ ^^^^^^^^^ Specify host.
25
27 # Exercise:
28 # -----
29 # Expand the functionality of this script
30 #+ so that it automatically e-mails a notification
31 #+ to the responsible ISP's contact address(es).
32 # Hint: use the "mail" command.
33
34 exit $?
35
36 # spam-lookup.sh chinatietong.com
37 #
                     A known spam domain.
38
39 # "crnet_mgr@chinatietong.com"
40 # "crnet_tec@chinatietong.com"
41 # "postmaster@chinatietong.com"
42
43
44 # For a more elaborate version of this script,
45 #+ see the SpamViz home page, http://www.spamviz.net/index.html.
```

Example 15-40. Analyzing a spam domain

```
1 #! /bin/bash
2 # is-spammer.sh: Identifying spam domains
3
4 # $Id: is-spammer, v 1.4 2004/09/01 19:37:52 mszick Exp $
5 # Above line is RCS ID info.
6 #
```

```
7 # This is a simplified version of the "is_spammer.bash
 8 #+ script in the Contributed Scripts appendix.
10 # is-spammer <domain.name>
12 # Uses an external program: 'dig'
13 # Tested with version: 9.2.4rc5
14
15 # Uses functions.
16 # Uses IFS to parse strings by assignment into arrays.
17 # And even does something useful: checks e-mail blacklists.
19 # Use the domain.name(s) from the text body:
20 # http://www.good_stuff.spammer.biz/just_ignore_everything_else
                           ____
21 #
22 # Or the domain.name(s) from any e-mail address:
23 # Really_Good_Offer@spammer.biz
24 #
25 # as the only argument to this script.
26 # (PS: have your Inet connection running)
27 #
28 # So, to invoke this script in the above two instances:
29 # is-spammer.sh spammer.biz
30
31
32 # Whitespace == :Space:Tab:Line Feed:Carriage Return:
33 WSP_IFS=$'\x20'$'\x09'$'\x0A'$'\x0D'
35 # No Whitespace == Line Feed:Carriage Return
36 No_WSP=$'\x0A'$'\x0D'
37
38 # Field separator for dotted decimal ip addresses
39 ADR_IFS=${No_WSP}'.'
40
41 # Get the dns text resource record.
42 # get_txt <error_code> <list_query>
43 get_txt() {
44
45
      # Parse $1 by assignment at the dots.
46
      local -a dns
47
      IFS=$ADR_IFS
48
      dns=( $1 )

      echo $(chk_adr ${rev_dns} 'unconfirmed.dsbl.org')
126
127 else
128
      echo
       echo 'Could not use that address.'
129
130 fi
131
132 exit 0
133
134 # Exercises:
135 # --
136
137 # 1) Check arguments to script,
138 # and exit with appropriate error message if necessary.
```

```
139
140 # 2) Check if on-line at invocation of script,
141 # and exit with appropriate error message if necessary.
142
143 # 3) Substitute generic variables for "hard-coded" BHL domains.
144
145 # 4) Set a time-out for the script using the "+time=" option
146 to the 'dig' command.
```

For a much more elaborate version of the above script, see Example A-30.

traceroute

Trace the route taken by packets sent to a remote host. This command works within a LAN, WAN, or over the Internet. The remote host may be specified by an IP address. The output of this command may be filtered by grep or sed in a pipe.

```
bash$ traceroute 81.9.6.2

traceroute to 81.9.6.2 (81.9.6.2), 30 hops max, 38 byte packets

1 tc43.xjbnnbrb.com (136.30.178.8) 191.303 ms 179.400 ms 179.767 ms

2 or0.xjbnnbrb.com (136.30.178.1) 179.536 ms 179.534 ms 169.685 ms

3 192.168.11.101 (192.168.11.101) 189.471 ms 189.556 ms *
```

ping

Broadcast an "ICMP ECHO_REQUEST" packet to another machine, either on a local or remote network. This is a diagnostic tool for testing network connections, and it should be used with caution.

```
bash$ ping localhost
PING localhost.localdomain (127.0.0.1) from 127.0.0.1 : 56(84) bytes of data.
64 bytes from localhost.localdomain (127.0.0.1): icmp_seq=0 ttl=255 time=709 usec
64 bytes from localhost.localdomain (127.0.0.1): icmp_seq=1 ttl=255 time=286 usec
--- localhost.localdomain ping statistics ---
2 packets transmitted, 2 packets received, 0% packet loss
round-trip min/avg/max/mdev = 0.286/0.497/0.709/0.212 ms
```

A successful **ping** returns an <u>exit status</u> of 0. This can be tested for in a script.

```
1 HNAME=nastyspammer.com
2 # HNAME=$HOST  # Debug: test for localhost.
3 count=2 # Send only two pings.
4
5 if [[ `ping -c $count "$HNAME"` ]]
6 then
7 echo ""$HNAME" still up and broadcasting spam your way."
8 else
9 echo ""$HNAME" seems to be down. Pity."
10 fi
```

whois

Perform a DNS (Domain Name System) lookup. The -h option permits specifying which particular *whois* server to query. See <u>Example 4-6</u> and <u>Example 15-39</u>.

finger

Retrieve information about users on a network. Optionally, this command can display a user's ~/.plan, ~/.project, and ~/.forward files, if present.

```
bash$ finger

Login Name Tty Idle Login Time Office Office Phone
bozo Bozo Bozeman tty1 8 Jun 25 16:59
bozo Bozo Bozeman ttyp0 Jun 25 16:59
bozo Bozo Bozeman ttyp1 Jun 25 17:07
```

```
bash$ finger bozo
Login: bozo
Name: Bozo Bozeman
Directory: /home/bozo
Office: 2355 Clown St., 543-1234
On since Fri Aug 31 20:13 (MST) on tty1 1 hour 38 minutes idle
On since Fri Aug 31 20:13 (MST) on pts/0 12 seconds idle
On since Fri Aug 31 20:13 (MST) on pts/1
On since Fri Aug 31 20:31 (MST) on pts/2 1 hour 16 minutes idle
No mail.
No Plan.
```

Out of security considerations, many networks disable **finger** and its associated daemon. [1]

chfn

Change information disclosed by the **finger** command.

vrfy

Verify an Internet e-mail address.

This command seems to be missing from newer Linux distros.

Remote Host Access

sx, rx

The **sx** and **rx** command set serves to transfer files to and from a remote host using the *xmodem* protocol. These are generally part of a communications package, such as **minicom**.

sz, rz

The sz and rz command set serves to transfer files to and from a remote host using the *zmodem* protocol. *Zmodem* has certain advantages over *xmodem*, such as faster transmission rate and resumption of interrupted file transfers. Like sx and rx, these are generally part of a communications package.

ftp

Utility and protocol for uploading / downloading files to or from a remote host. An ftp session can be automated in a script (see <u>Example 18-6</u>, <u>Example A-4</u>, and <u>Example A-13</u>).

uucp, uux, cu

uucp: *UNIX to UNIX copy*. This is a communications package for transferring files between UNIX servers. A shell script is an effective way to handle a **uucp** command sequence.

Since the advent of the Internet and e-mail, **uucp** seems to have faded into obscurity, but it still exists and remains perfectly workable in situations where an Internet connection is not available or appropriate. The advantage of **uucp** is that it is fault-tolerant, so even if there is a service interruption the copy operation will resume where it left off when the connection is restored.

uux: *UNIX to UNIX execute*. Execute a command on a remote system. This command is part of the **uucp** package.

cu: Call Up a remote system and connect as a simple terminal. It is a sort of dumbed-down version of telnet. This command is part of the **uucp** package.

telnet

Utility and protocol for connecting to a remote host.

The *telnet* protocol contains security holes and should therefore probably be avoided. Its use within a shell script is *not* recommended.

wget

The **wget** utility *non-interactively* retrieves or downloads files from a Web or ftp site. It works well in a script.

```
1 wget -p http://www.xyz23.com/file01.html
2 # The -p or --page-requisite option causes wget to fetch all files
3 #+ required to display the specified page.
4
5 wget -r ftp://ftp.xyz24.net/~bozo/project_files/ -O $SAVEFILE
6 # The -r option recursively follows and retrieves all links
7 #+ on the specified site.
8
9 wget -c ftp://ftp.xyz25.net/bozofiles/filename.tar.bz2
10 # The -c option lets wget resume an interrupted download.
11 # This works with ftp servers and many HTTP sites.
```

Example 15-41. Getting a stock quote

```
1 #!/bin/bash
 2 # quote-fetch.sh: Download a stock quote.
3
4
5 E_NOPARAMS=66
7 if [ -z "$1" ] # Must specify a stock (symbol) to fetch.
8 then echo "Usage: `basename $0` stock-symbol"
9 exit $E_NOPARAMS
10 fi
11
12 stock_symbol=$1
13
14 file_suffix=.html
15 # Fetches an HTML file, so name it appropriately.
16 URL='http://finance.yahoo.com/q?s='
17 # Yahoo finance board, with stock query suffix.
18
19 # ----
20 wget -0 ${stock_symbol}${file_suffix} "${URL}${stock_symbol}"
22
2.3
24 # To look up stuff on http://search.yahoo.com:
26 # URL="http://search.yahoo.com/search?fr=ush-news&p=${query}"
27 # wget -O "$savefilename" "${URL}"
29 # Saves a list of relevant URLs.
31 exit $?
32
33 # Exercises:
34 # -----
36 # 1) Add a test to ensure the user running the script is on-line.
37 #
     (Hint: parse the output of 'ps -ax' for "ppp" or "connect."
38 #
39 # 2) Modify this script to fetch the local weather report,
40 #+ taking the user's zip code as an argument.
```

See also Example A-32 and Example A-33.

lynx

The **lynx** Web and file browser can be used inside a script (with the -dump option) to retrieve a file from a Web or ftp site non-interactively.

```
1 lynx -dump http://www.xyz23.com/file01.html >$SAVEFILE
```

With the -traversal option, **lynx** starts at the HTTP URL specified as an argument, then "crawls" through all links located on that particular server. Used together with the -crawl option, outputs page text to a log file.

rlogin

Remote login, initates a session on a remote host. This command has security issues, so use <u>ssh</u> instead.

rsh

Remote shell, executes command(s) on a remote host. This has security issues, so use **ssh** instead.

rcp

Remote copy, copies files between two different networked machines.

rsync

Remote synchronize, updates (synchronizes) files between two different networked machines.

```
bash$ rsync -a ~/sourcedir/*txt /node1/subdirectory/
```

Example 15-42. Updating FC4

```
1 #!/bin/bash
 2 # fc4upd.sh
 4 # Script author: Frank Wang.
 5 # Slight stylistic modifications by ABS Guide author.
 6 # Used in ABS Guide with permission.
 8
 9 # Download Fedora Core 4 update from mirror site using rsync.
10 # Should also work for newer Fedora Cores -- 5, 6, . .
11 # Only download latest package if multiple versions exist,
12 #+ to save space.
14 URL=rsync://distro.ibiblio.org/fedora-linux-core/updates/
15 # URL=rsync://ftp.kddilabs.jp/fedora/core/updates/

       "Fedora update mirrored with failure code: $RET"
215 fi
216
217 exit $RET
```

See also Example A-34.

Using rcp, rsync, and similar utilities with security implications in a shell script may not be advisable. Consider, instead, using ssh, scp, or an expect script.

ssh

Secure shell, logs onto a remote host and executes commands there. This secure replacement for **telnet**, **rlogin**, **rcp**, and **rsh** uses identity authentication and encryption. See its <u>manpage</u> for details.

```
1 #!/bin/bash
2 # remote.bash: Using ssh.
4 # This example by Michael Zick.
5 # Used with permission.
 7
 8 # Presumptions:
 9 #
10 \# fd-2 isn't being captured ( '2>/dev/null' ).
11 # ssh/sshd presumes stderr ('2') will display to user.
12 #
     sshd is running on your machine.
13 #
14 # For any 'standard' distribution, it probably is,
15 #+ and without any funky ssh-keygen having been done.
17 # Try ssh to your machine from the command line:
18 #
19 # $ ssh $HOSTNAME
20 # Without extra set-up you'll be asked for your password.
21 # enter password
22 # when done, $ exit
23 #
24 # Did that work? If so, you're ready for more fun.
26 # Try ssh to your machine as 'root':
2.7 #
28 # $ ssh -1 root $HOSTNAME
29 # When asked for password, enter root's, not yours.
30 #
             Last login: Tue Aug 10 20:25:49 2004 from localhost.localdomain
31 # Enter 'exit' when done.
32
33 # The above gives you an interactive shell.
34 # It is possible for sshd to be set up in a 'single command' mode,
35 #+ but that is beyond the scope of this example.
36 # The only thing to note is that the following will work in
37 #+ 'single command' mode.
38
39
40 # A basic, write stdout (local) command.
41
42 ls -1
43
44 # Now the same basic command on a remote machine.
45 # Pass a different 'USERNAME' 'HOSTNAME' if desired:
46 USER=${USERNAME:-$(whoami)}
47 HOST=${HOSTNAME:-$(hostname)}
48
49 # Now excute the above command line on the remote host,
50 #+ with all transmissions encrypted.
52 ssh -l ${USER} ${HOST} " ls -l "
54 # The expected result is a listing of your username's home
55 \text{ \#+ directory on the remote machine.}
56 \# To see any difference, run this script from somewhere
57 #+ other than your home directory.
58
59 # In other words, the Bash command is passed as a quoted line
60 #+ to the remote shell, which executes it on the remote machine.
61 # In this case, sshd does 'bash -c "ls -l" ' on your behalf.
62
63 # For information on topics such as not having to enter a
64 #+ password/passphrase for every command line, see
65 #+ man ssh
66 #+ man ssh-keygen
```

```
67 #+
      man sshd_config.
68
69 exit 0
```

1 Within a loop, ssh may cause unexpected behavior. According to a <u>Usenet post</u> in the comp.unix shell archives, ssh inherits the loop's stdin. To remedy this, pass ssh either the -n or -f option.

Thanks, Jason Bechtel, for pointing this out.

scp

Secure copy, similar in function to rcp, copies files between two different networked machines, but does so using authentication, and with a security level similar to ssh.

Local Network

write

This is a utility for terminal-to-terminal communication. It allows sending lines from your terminal (console or *xterm*) to that of another user. The <u>mesg</u> command may, of course, be used to disable write access to a terminal

Since **write** is interactive, it would not normally find use in a script.

netconfig

A command-line utility for configuring a network adapter (using DHCP). This command is native to Red Hat centric Linux distros.

Mail

mail

Send or read e-mail messages.

This stripped-down command-line mail client works fine as a command embedded in a script.

Example 15-44. A script that mails itself

```
1 #!/bin/sh
 2 # self-mailer.sh: Self-mailing script
 4 adr=${1:-`whoami`} # Default to current user, if not specified.
 5 # Typing 'self-mailer.sh wisequy@superdupergenius.com'
 6 #+ sends this script to that addressee.
 7 # Just 'self-mailer.sh' (no argument) sends the script
 8 #+ to the person invoking it, for example, bozo@localhost.localdomain.
 9 #
10 # For more on the ${parameter:-default} construct,
11 #+ see the "Parameter Substitution" section
12 #+ of the "Variables Revisited" chapter.
13
14 # ======
15 cat $0 | mail -s "Script \"`basename $0`\" has mailed itself to you." "$adr"
17
18 # ---
19 # Greetings from the self-mailing script.
20 # A mischievous person has run this script,
21 #+ which has caused it to mail itself to you.
22 # Apparently, some people have nothing better
23 #+ to do with their time.
```

```
24 # -----25
25 26 echo "At `date`, script \"`basename $0`\" mailed to "$adr"."
27 28 exit 0
```

mailto

Similar to the **mail** command, **mailto** sends e-mail messages from the command line or in a script. However, **mailto** also permits sending MIME (multimedia) messages.

vacation

This utility automatically replies to e-mails that the intended recipient is on vacation and temporarily unavailable. It runs on a network, in conjunction with **sendmail**, and is not applicable to a dial-up POPmail account.

Notes

[1]

A *daemon* is a background process not attached to a terminal session. Daemons perform designated services either at specified times or explicitly triggered by certain events.

The word "daemon" means ghost in Greek, and there is certainly something mysterious, almost supernatural, about the way UNIX daemons wander about behind the scenes, silently carrying out their appointed tasks.

15.7. Terminal Control Commands

Command affecting the console or terminal

tput

Initialize terminal and/or fetch information about it from terminfo data. Various options permit certain terminal operations. **tput clear** is the equivalent of **clear**, below. **tput reset** is the equivalent of <u>reset</u>, below. **tput sgr0** also resets the terminal, but without clearing the screen.

```
bash$ tput longname xterm terminal emulator (XFree86 4.0 Window System)
```

Issuing a **tput cup X Y** moves the cursor to the (X,Y) coordinates in the current terminal. A **clear** to erase the terminal screen would normally precede this.

Note that stty offers a more powerful command set for controlling a terminal.

infocmp

This command prints out extensive information about the current terminal. It references the *terminfo* database.

```
bash$ infocmp
# Reconstructed via infocmp from file:
/usr/share/terminfo/r/rxvt
rxvt|rxvt terminal emulator (X Window System),
    am, bce, eo, km, mir, msgr, xenl, xon,
    colors#8, cols#80, it#8, lines#24, pairs#64,
    acsc=``aaffggjjkkllmmnnooppqqrrssttuuvvwwxxyyzz{{||}}~~,
    bel=^G, blink=\E[5m, bold=\E[1m,
    civis=\E[?251,
    clear=\E[H\E[2J, cnorm=\E[?25h, cr=^M,
    ...
```

reset

Reset terminal parameters and clear text screen. As with **clear**, the cursor and prompt reappear in the upper lefthand corner of the terminal.

clear

The **clear** command simply clears the text screen at the console or in an *xterm*. The prompt and cursor reappear at the upper lefthand corner of the screen or xterm window. This command may be used either at the command line or in a script. See <u>Example 10-25</u>.

script

This utility records (saves to a file) all the user keystrokes at the command line in a console or an xterm window. This, in effect, creates a record of a session.

Communications Commands Up Math Commands

Advanced Bash-Scripting Guide: An in-depth exploration of the art of shell scripting

Prev Chapter 15. External Filters, Programs and Commands

<u>Next</u>

15.8. Math Commands

"Doing the numbers"

factor

Decompose an integer into prime factors.

```
bash$ factor 27417
27417: 3 13 19 37
```

bc

Bash can't handle floating point calculations, and it lacks operators for certain important mathematical functions. Fortunately, **bc** comes to the rescue.

Not just a versatile, arbitrary precision calculation utility, **bc** offers many of the facilities of a programming language.

bc has a syntax vaguely resembling C.

Since it is a fairly well-behaved UNIX utility, and may therefore be used in a <u>pipe</u>, **bc** comes in handy in scripts.

Here is a simple template for using **bc** to calculate a script variable. This uses command substitution.

```
variable=$(echo "OPTIONS; OPERATIONS" | bc)
```

Example 15-45. Monthly Payment on a Mortgage

```
1 #!/bin/bash
 2 # monthlypmt.sh: Calculates monthly payment on a mortgage.
 4
 5 # This is a modification of code in the
 6 #+ "mcalc" (mortgage calculator) package,
7 #+ by Jeff Schmidt
8 #+ and
9 #+ Mendel Cooper (yours truly, the author of the ABS Guide).
10 # http://www.ibiblio.org/pub/Linux/apps/financial/mcalc-1.6.tar.gz [15k]
11
12 echo
13 echo "Given the principal, interest rate, and term of a mortgage,"
14 echo "calculate the monthly payment."
15
16 bottom=1.0
17
18 echo
19 echo -n "Enter principal (no commas) "
20 read principal
21 echo -n "Enter interest rate (percent) " # If 12%, enter "12", not ".12".
22 read interest_r
23 echo -n "Enter term (months) "
24 read term
25
26
27 interest_r=$(echo "scale=9; $interest_r/100.0" | bc) # Convert to decimal.
                                ^^^^^^^ Divide by 100.
                    #
```

```
29
                   # "scale" determines how many decimal places.
30
31 interest_rate=$(echo "scale=9; $interest_r/12 + 1.0" | bc)
34 top=$(echo "scale=9; $principal*$interest_rate^$term" | bc)
35
            #
36
                        Standard formula for figuring interest.
37
38 echo; echo "Please be patient. This may take a while."
39
40 let "months = $term - 1"
41 # ==========
                                _____
42 for ((x=\$months; x > 0; x--))
43 do
   bot=$(echo "scale=9; $interest_rate^$x" | bc)
     bottom=$(echo "scale=9; $bottom+$bot" | bc)
45
46 # bottom = $(($bottom + $bot"))
47 done
48 # =========
49
50 # ---
51 # Rick Boivie pointed out a more efficient implementation
52 #+ of the above loop, which decreases computation time by 2/3.
54 # for ((x=1; x \le \$months; x++))
55 # do
56 # bottom=$(echo "scale=9; $bottom * $interest_rate + 1" | bc)
57 # done
58
59
60 # And then he came up with an even more efficient alternative,
61 #+ one that cuts down the run time by about 95%!
63 # bottom=`{
     echo "scale=9; bottom=$bottom; interest_rate=$interest_rate"
        for ((x=1; x \le \$months; x++))
66 #
67 #
            echo 'bottom = bottom * interest_rate + 1'
      done
68 #
      echo 'bottom'
69 #
70 # } | bc` # Embeds a 'for loop' within command substitution.
71 # -----
72 # On the other hand, Frank Wang suggests:
73 # bottom=$(echo "scale=9; ($interest_rate^$term-1)/($interest_rate-1)" | bc)
74
75 # Because . . .
76 # The algorithm behind the loop
77 #+ is actually a sum of geometric proportion series.
78 # The sum formula is e0(1-q^n)/(1-q),
79 #+ where e0 is the first element and q=e(n+1)/e(n)
80 #+ and n is the number of elements.
81 # ----
82
83
84 # let "payment = $top/$bottom"
85 payment=$(echo "scale=2; $top/$bottom" | bc)
86
   # Use two decimal places for dollars and cents.
87
88 echo
89 echo "monthly payment = \$$payment" # Echo a dollar sign in front of amount.
90 echo
91
92
93 exit 0
94
```

```
95
96 # Exercises:
97 # 1) Filter input to permit commas in principal amount.
98 # 2) Filter input to permit interest to be entered as percent or decimal.
99 # 3) If you are really ambitious,
100 #+ expand this script to print complete amortization tables.
```

Example 15-46. Base Conversion

```
1 #!/bin/bash
 3 # Shellscript: base.sh - print number to different bases (Bourne Shell)

```

An alternate method of invoking **bc** involves using a <u>here document</u> embedded within a <u>command substitution</u> block. This is especially appropriate when a script needs to pass a list of options and commands to **bc**.

```
1 variable=`bc << LIMIT_STRING
2 options
3 statements</pre>
```

```
4 operations
5 LIMIT_STRING
6 `
7
8 ...or...
9
10
11 variable=$(bc << LIMIT_STRING
12 options
13 statements
14 operations
15 LIMIT_STRING
16 )</pre>
```

Example 15-47. Invoking bc using a here document

```
1 #!/bin/bash
 2 # Invoking 'bc' using command substitution
 3 # in combination with a 'here document'.
 6 var1=`bc << EOF
 7 18.33 * 19.78
8 EOF
10 echo $var1 # 362.56
11
12
13 # $( ... ) notation also works.
14 v1=23.53
15 v2=17.881
16 v3=83.501
17 v4=171.63
18
19 var2=$ (bc << EOF
20 \text{ scale} = 4
21 a = ( $v1 + $v2 )
22 b = ($v3 * $v4)
23 a * b + 15.35
24 EOF
25)
26 echo $var2 # 593487.8452
27
28
29 var3=$ (bc -1 << EOF
30 \text{ scale} = 9
31 s (1.7)
32 EOF
33)
34 # Returns the sine of 1.7 radians.
35 # The "-1" option calls the 'bc' math library.
36 echo $var3
                # .991664810
37
38
39 # Now, try it in a function...
40 hypotenuse () # Calculate hypotenuse of a right triangle.
41 {
                   \# c = sqrt(a^2 + b^2)
42 hyp=$ (bc -1 << EOF
43 \text{ scale} = 9
44 sqrt ( $1 * $1 + $2 * $2 )
45 EOF
46)
47 # Can't directly return floating point values from a Bash function.
48 # But, can echo-and-capture:
```

```
49 echo "$hyp"
50 }
51
52 hyp=$(hypotenuse 3.68 7.31)
53 echo "hypotenuse = $hyp" # 8.184039344
54
55
56 exit 0
```

Example 15-48. Calculating PI

```
1 #!/bin/bash
2 # cannon.sh: Approximating PI by firing cannonballs.
4 # This is a very simple instance of a "Monte Carlo" simulation:
 5 #+ a mathematical model of a real-life event,
 6 #+ using pseudorandom numbers to emulate random chance.
 8 # Consider a perfectly square plot of land, 10000 units on a side.
 9 # This land has a perfectly circular lake in its center,
10 #+ with a diameter of 10000 units.
11 # The plot is actually mostly water, except for land in the four corners.
     (Think of it as a square with an inscribed circle.)
14 # We will fire iron cannonballs from an old-style cannon
15 #+ at the square.
16 # All the shots impact somewhere on the square,
17 #+ either in the lake or on the dry corners.
18 # Since the lake takes up most of the area,
19 #+ most of the shots will SPLASH! into the water.
20 # Just a few shots will THUD! into solid ground
21 #+ in the four corners of the square.
22 #
23 # If we take enough random, unaimed shots at the square,
24 #+ Then the ratio of SPLASHES to total shots will approximate
25 \#+ the value of PI/4.
26 #
27 # The reason for this is that the cannon is actually shooting
28 #+ only at the upper right-hand quadrant of the square,
29 #+ i.e., Quadrant I of the Cartesian coordinate plane.
30 # (The previous explanation was a simplification.)
31 #
32 # Theoretically, the more shots taken, the better the fit.
33 # However, a shell script, as opposed to a compiled language
34 #+ with floating-point math built in, requires a few compromises.
35 # This tends to lower the accuracy of the simulation, of course.
38 DIMENSION=10000 # Length of each side of the plot.
39
                    # Also sets ceiling for random integers generated.
40
41 MAXSHOTS=1000 # Fire this many shots.
                   # 10000 or more would be better, but would take too long.
43 PMULTIPLIER=4.0 # Scaling factor to approximate PI.
45 get_random ()
47 SEED=$(head -n 1 /dev/urandom | od -N 1 | awk '{ print $2 }')
48 RANDOM=$SEED
                                                 # From "seeding-random.sh"
49
                                                 #+ example script.
50 let "rnum = $RANDOM % $DIMENSION"
                                                 # Range less than 10000.

116
117 exit 0
```

```
118
119 # One might well wonder whether a shell script is appropriate for
120 #+ an application as complex and computation-intensive as a simulation.
121 #
122 # There are at least two justifications.
123 # 1) As a proof of concept: to show it can be done.
124 # 2) To prototype and test the algorithms before rewriting
125 #+ it in a compiled high-level language.
```

dc

The **dc** (**d**esk **c**alculator) utility is stack-oriented and uses RPN ("Reverse Polish Notation"). Like **bc**, it has much of the power of a programming language.

Most persons avoid **dc**, since it requires non-intuitive RPN input. Yet, it has its uses.

Example 15-49. Converting a decimal number to hexadecimal

```
1 #!/bin/bash
 2 # hexconvert.sh: Convert a decimal number to hexadecimal.
 4 E_NOARGS=65 # Command-line arg missing.
 5 BASE=16 # Hexadecimal.
 6
 7 if [ -z "$1" ]
 8 then
9 echo "Usage: $0 number"
10 exit $E_NOARGS
11 # Need a command line argument.
12 fi
13 # Exercise: add argument validity checking.
14
15
16 hexcvt ()
17 {
18 if [ -z "$1" ]
19 then
20 echo 0
21
    return # "Return" 0 if no arg passed to function.
22 fi
24 echo ""$1" "$BASE" o p" | dc
                     "o" sets radix (numerical base) of output.
26 #
                      "p" prints the top of stack.
27 # See 'man dc' for other options.
28 return
29 }
30
31 hexcvt "$1"
32
33 exit 0
```

Studying the *info* page for **dc** is a painful path to understanding its intricacies. There seems to be a small, select group of *dc wizards* who delight in showing off their mastery of this powerful, but arcane utility.

```
bash$ echo "16i[q]sa[ln0=aln100%Pln100/snlbx]sbA0D68736142snlbxq" | dc"
Bash
```

Example 15-50. Factoring

```
1 #!/bin/bash
  2 # factr.sh: Factor a number
             # Will not work for number smaller than this.
  4 MIN=2
  5 E_NOARGS=65
  6 E_TOOSMALL=66
 8 if [ -z $1 ]
 9 then
 10 echo "Usage: $0 number"
 11 exit $E_NOARGS
 12 fi
 13
 14 if [ "$1" -lt "$MIN" ]
 15 then
    echo "Number to factor must be $MIN or greater."
 17
     exit $E_TOOSMALL
 18 fi
 19
 20 # Exercise: Add type checking (to reject non-integer arg).
 21
 22 echo "Factors of $1:"
 23 # -----
 24 echo "$1[p]s2[lip/dli%0=1dvsr]s12sid2%0=13sidvsr[dli%0=1lrli2+dsi!>.]ds.xd1<2"|dc
 26 # Above line of code written by Michel Charpentier <charpov@cs.unh.edu>.
 27 # Used in ABS Guide with permission (thanks!).
29 exit 0
```

awk

Yet another way of doing floating point math in a script is using <u>awk's</u> built-in math functions in a <u>shell wrapper</u>.

Example 15-51. Calculating the hypotenuse of a triangle

```
1 #!/bin/bash
 2 # hypotenuse.sh: Returns the "hypotenuse" of a right triangle.
           (square root of sum of squares of the "legs")
 5 ARGS=2
                        # Script needs sides of triangle passed.
 6 E BADARGS=65
                        # Wrong number of arguments.
8 if [ $# -ne "$ARGS" ] # Test number of arguments to script.
10 echo "Usage: `basename $0` side_1 side_2"
11 exit $E_BADARGS
12 fi
13
15 AWKSCRIPT=' { printf( "%3.7f\n", sqrt($1*$1 + $2*$2) ) } '
16 #
              command(s) / parameters passed to awk
17
18
19 # Now, pipe the parameters to awk.
     echo -n "Hypotenuse of $1 and $2 = "
2.0
      echo $1 $2 | awk "$AWKSCRIPT"
21
     ^^^^^
22 #
23 # An echo-and-pipe is an easy way of passing shell parameters to awk.
```

25 exit 0
26
27 # Exercise: Rewrite this script using 'bc' rather than awk.
28 # Which method is more intuitive?

15.9. Miscellaneous Commands

Command that fit in no special category

jot, seq

These utilities emit a sequence of integers, with a user-selectable increment.

The default separator character between each integer is a newline, but this can be changed with the -s option.

```
bash$ seq 5
1
2
3
4
5

bash$ seq -s : 5
1:2:3:4:5
```

Both **jot** and **seq** come in handy in a <u>for loop</u>.

Example 15-52. Using seq to generate loop arguments

```
1 #!/bin/bash
2 # Using "seg"
3
4 echo
6 for a in `seq 80` # or for a in $( seq 80 )
7 # Same as for a in 1 2 3 4 5 ... 80 (saves much typing!).
8 # May also use 'jot' (if present on system).
9 do
10 echo -n "$a "
11 done # 1 2 3 4 5 ... 80
12 # Example of using the output of a command to generate
13 # the [list] in a "for" loop.
14
15 echo; echo
16
17
18 COUNT=80 # Yes, 'seq' also accepts a replaceable parameter.
19
20 for a in `seq $COUNT` # or for a in $( seq $COUNT )
21 do
22 echo -n "$a "
23 done # 1 2 3 4 5 ... 80
24
25 echo; echo
26
27 BEGIN=75
28 END=80
29
30 for a in `seq $BEGIN $END`
31 \# Giving "seq" two arguments starts the count at the first one,
32 #+ and continues until it reaches the second.
33 do
34 echo -n "$a "
```

```
35 done # 75 76 77 78 79 80
37 echo; echo
38
39 BEGIN=45
40 INTERVAL=5
41 END=80
42
43 for a in `seq $BEGIN $INTERVAL $END`
44 # Giving "seq" three arguments starts the count at the first one,
45 #+ uses the second for a step interval,
46 #+ and continues until it reaches the third.
47 do
48 echo -n "$a "
49 done # 45 50 55 60 65 70 75 80
51 echo; echo
52
53 exit 0
```

A simpler example:

```
1 # Create a set of 10 files,
2 #+ named file.1, file.2 . . . file.10.
3 COUNT=10
4 PREFIX=file
5
6 for filename in `seq $COUNT`
7 do
8  touch $PREFIX.$filename
9  # Or, can do other operations,
10  #+ such as rm, grep, etc.
11 done
```

Example 15-53. Letter Count"

```
1 #!/bin/bash
 2 # letter-count.sh: Counting letter occurrences in a text file.
 3 # Written by Stefano Palmeri.
 4 # Used in ABS Guide with permission.
 5 # Slightly modified by document author.
7 MINARGS=2
                      # Script requires at least two arguments.
8 E_BADARGS=65
9 FILE=$1
11 let LETTERS=$#-1  # How many letters specified (as command-line args).
                      # (Subtract 1 from number of command line args.)
12
13
14
15 show_help(){
16 echo
             echo Usage: `basename $0` file letters
17
             echo Note: `basename $0` arguments are case sensitive.
18
             echo Example: `basename $0` foobar.txt G n U L i N U x.
19
20
        echo
21 }
23 # Checks number of arguments.
24 if [ $# -lt $MINARGS ]; then
    echo
25
26
     echo "Not enough arguments."
27 echo
```

```
28
   show_help
29 exit $E_BADARGS
30 fi
31
32
33 # Checks if file exists.
34 if [ ! -f $FILE ]; then
     echo "File \"$FILE\" does not exist."
36
      exit $E_BADARGS
37 fi
38
39
40
41 # Counts letter occurrences .
42 for n in `seq $LETTERS`; do
        shift
        if [[ `echo -n "$1" | wc -c` -eq 1 ]]; then
44
                                                             # Checks arg.
              echo "$1" -\> `cat $FILE | tr -cd "$1" | wc -c` # Counting.
4.5
46
       else
47
             echo "$1 is not a single char."
48 fi
49 done
50
51 exit $?
52
53 # This script has exactly the same functionality as letter-count2.sh,
54 #+ but executes faster.
55 # Why?
```

Somewhat more capable than *seq*, **jot** is a classic UNIX utility that is not normally included in a standard Linux distro. However, the source *rpm* is available for download from the <u>MIT repository</u>.

Unlike *seq*, **jot** can generate a sequence of random numbers, using the -r option.

```
bash$ jot -r 3 999
1069
1272
1428
```

getopt

The **getopt** command parses command-line options preceded by a <u>dash</u>. This external command corresponds to the <u>getopts</u> Bash builtin. Using **getopt** permits handling long options by means of the -1 flag, and this also allows parameter reshuffling.

Example 15-54. Using getopt to parse command-line options

```
1 #!/bin/bash
2 # Using getopt
3
4 # Try the following when invoking this script:
5 # sh ex33a.sh -a
6 # sh ex33a.sh -abc
7 # sh ex33a.sh -a -b -c
8 # sh ex33a.sh -d
9 # sh ex33a.sh -d
9 # sh ex33a.sh -dXYZ
10 # sh ex33a.sh -dXYZ
11 # sh ex33a.sh -abcd
12 # sh ex33a.sh -abcd
13 # sh ex33a.sh -abcd
13 # sh ex33a.sh -z
```

```
14 # sh ex33a.sh a
15 # Explain the results of each of the above.
16
17 E_OPTERR=65
18
19 if [ "$#" -eq 0 ]
20 then # Script needs at least one command-line argument.
21 echo "Usage $0 -[options a,b,c]"
22 exit $E_OPTERR
2.3 fi
2.4
25 set -- `getopt "abcd:" "$@"`
26 # Sets positional parameters to command-line arguments.
27 # What happens if you use "$*" instead of "$@"?
29 while [ ! -z "$1" ]
30 do
31 case "$1" in
    -a) echo "Option \"a\"";;
33
      -b) echo "Option \"b\"";;
     -c) echo "Option \"c\"";;
35 -d) echo "Option \"d\" $2";;
36 *) break;;
37 esac
38
39 shift
40 done
42 # It is usually better to use the 'getopts' builtin in a script.
43 # See "ex33.sh."
44
45 exit 0
```

See Example 9-14 for a simplified emulation of **getopt**.

run-parts

The **run-parts** command [1] executes all the scripts in a target directory, sequentially in ASCII-sorted filename order. Of course, the scripts need to have execute permission.

The <u>cron daemon</u> invokes **run-parts** to run the scripts in the /etc/cron.* directories.

yes

In its default behavior the **yes** command feeds a continuous string of the character y followed by a line feed to stdout. A **control-c** terminates the run. A different output string may be specified, as in **yes different string**, which would continually output different string to stdout.

One might well ask the purpose of this. From the command line or in a script, the output of **yes** can be redirected or piped into a program expecting user input. In effect, this becomes a sort of poor man's version of **expect**.

yes | fsck /dev/hda1 runs fsck non-interactively (careful!).

yes | rm -r dirname has same effect as rm -rf dirname (careful!).

- Caution advised when piping **yes** to a potentially dangerous system command, such as <u>fsck</u> or <u>fdisk</u>. It might have unintended consequences.
- The yes command parses variables. For example:

```
bash$ yes $BASH_VERSION

3.1.17(1)-release

3.1.17(1)-release

3.1.17(1)-release
```

```
3.1.17(1)-release
3.1.17(1)-release
. . .
```

This "feature" may not be particularly useful.

banner

Prints arguments as a large vertical banner to stdout, using an ASCII character (default '#'). This may be redirected to a printer for hardcopy.

printenv

Show all the environmental variables set for a particular user.

```
bash$ printenv | grep HOME
HOME=/home/bozo
```

lp

The **lp** and **lpr** commands send file(s) to the print queue, to be printed as hard copy. [2] These commands trace the origin of their names to the line printers of another era.

```
bash$ lp file1.txt or bash lp <file1.txt
```

It is often useful to pipe the formatted output from **pr** to **lp**.

```
bash$ pr -options file1.txt | lp
```

Formatting packages, such as groff and Ghostscript may send their output directly to lp.

```
bash$ groff -Tascii file.tr | lp
bash$ gs -options | lp file.ps
```

Related commands are **lpq**, for viewing the print queue, and **lprm**, for removing jobs from the print queue.

tee

[UNIX borrows an idea from the plumbing trade.]

This is a redirection operator, but with a difference. Like the plumber's *tee*, it permits "siponing off" *to a file* the output of a command or commands within a pipe, but without affecting the result. This is useful for printing an ongoing process to a file or paper, perhaps to keep track of it for debugging purposes.

```
1 cat listfile* | sort | tee check.file | uniq > result.file
```

(The file check . file contains the concatenated sorted "listfiles," before the duplicate lines are removed by <u>uniq</u>.)

mkfifo

This obscure command creates a *named pipe*, a temporary *first-in-first-out buffer* for transferring data between processes. [3] Typically, one process writes to the FIFO, and the other reads from it. See <u>Example A-15</u>.

```
1 #!/bin/bash
 2 # This short script by Omair Eshkenazi.
 3 # Used in ABS Guide with permission (thanks!).
 5 mkfifo pipe1
 6 mkfifo pipe2
 8 (cut -d' ' -f1 | tr "a-z" "A-Z") >pipe2 <pipe1 &
 9 ls -l | tr -s ' ' | cut -d' ' -f3,9- | tee pipe1 |
10 cut -d' ' -f2 | paste - pipe2
11
12 rm -f pipe1
13 rm -f pipe2
15 # No need to kill background processes when script terminates (why not?).
17 exit $?
18
19 Now, invoke the script and explain the output:
20 sh mkfifo-example.sh
2.1
22 4830.tar.gz
                       B070
23 pipel BOZO
24 pipe2 BOZO
25 mkfifo-example.sh BOZO
26 Mixed.msg BOZO
```

pathchk

This command checks the validity of a filename. If the filename exceeds the maximum allowable length (255 characters) or one or more of the directories in its path is not searchable, then an error message results.

Unfortunately, **pathchk** does not return a recognizable error code, and it is therefore pretty much useless in a script. Consider instead the <u>file test operators</u>.

dd

This is the somewhat obscure and much feared *data duplicator* command. Originally a utility for exchanging data on magnetic tapes between UNIX minicomputers and IBM mainframes, this command still has its uses. The **dd** command simply copies a file (or stdin/stdout), but with conversions. Possible conversions are ASCII/EBCDIC, [4] upper/lower case, swapping of byte pairs between input and output, and skipping and/or truncating the head or tail of the input file.

```
1 # Converting a file to all uppercase:
2
3 dd if=$filename conv=ucase > $filename.uppercase
4 # lcase # For lower case conversion
```

Some basic options to **dd** are:

```
    ◊ if=INFILE
    INFILE is the source file.
    ◊ of=OUTFILE
    OUTFILE is the target file, the file that will have the data written to it.
    ◊ bs=BLOCKSIZE
```

This is the size of each block of data being read and written, usually a power of 2. ♦ skip=BLOCKS How many blocks of data to skip in INFILE before starting to copy. This is useful when the INFILE has "garbage" or garbled data in its header or when it is desirable to copy only a portion of the INFILE.

♦ seek=BLOCKS

How many blocks of data to skip in OUTFILE before starting to copy, leaving blank data at beginning of OUTFILE.

♦ count=BLOCKS

Copy only this many blocks of data, rather than the entire INFILE.

♦ conv=CONVERSION

Type of conversion to be applied to INFILE data before copying operation.

A dd --help lists all the options this powerful utility takes.

Example 15-55. A script that copies itself

```
1 #!/bin/bash
2 # self-copy.sh
3
4 # This script copies itself.
5
6 file_subscript=copy
7
8 dd if=$0 of=$0.$file_subscript 2>/dev/null
9 # Suppress messages from dd: ^^^^^^^^
10
11 exit $?
```

Example 15-56. Exercising dd

```
1 #!/bin/bash
 2 # exercising-dd.sh
4 # Script by Stephane Chazelas.
 5 # Somewhat modified by ABS Guide author.
7 infile=$0 # This script.
8 outfile=log.txt # This output file left behind.
9 n=3
10 p=5
11
12 dd if=\infe of=\intoutfile bs=1 skip=((n-1)) count=((p-n+1)) 2> /dev/null
13 # Extracts characters n to p (3 to 5) from this script.
14
15 # -----
16
17 echo -n "hello world" | dd cbs=1 conv=unblock 2> /dev/null
18 # Echoes "hello world" vertically.
19 # Why? Newline after each character dd emits.
20
21 exit 0
```

To demonstrate just how versatile **dd** is, let's use it to capture keystrokes.

Example 15-57. Capturing Keystrokes

```
1 #!/bin/bash
 2 # dd-keypress.sh: Capture keystrokes without needing to press ENTER.
5 keypresses=4
                                    # Number of keypresses to capture.
8 old_tty_setting=$(stty -g)
                                   # Save old terminal settings.
10 echo "Press $keypresses keys."
11 stty -icanon -echo
                                  # Disable canonical mode.
                                    # Disable local echo.
13 keys=$(dd bs=1 count=$keypresses 2> /dev/null)
14 # 'dd' uses stdin, if "if" (input file) not specified.
16 stty "$old_tty_setting"
                                   # Restore old terminal settings.
17
18 echo "You pressed the \"$keys\" keys."
19
20 # Thanks, Stephane Chazelas, for showing the way.
21 exit 0
```

The **dd** command can do random access on a data stream.

```
1 echo -n . | dd bs=1 seek=4 of=file conv=notrunc
2 # The "conv=notrunc" option means that the output file
3 #+ will not be truncated.
4
5 # Thanks, S.C.
```

The **dd** command can copy raw data and disk images to and from devices, such as floppies and tape drives (Example A-5). A common use is creating boot floppies.

dd if=kernel-image of=/dev/fd0H1440

Similarly, **dd** can copy the entire contents of a floppy, even one formatted with a "foreign" OS, to the hard drive as an image file.

```
dd if=/dev/fd0 of=/home/bozo/projects/floppy.img
```

Other applications of **dd** include initializing temporary swap files (<u>Example 28-2</u>) and ramdisks (<u>Example 28-3</u>). It can even do a low-level copy of an entire hard drive partition, although this is not necessarily recommended.

People (with presumably nothing better to do with their time) are constantly thinking of interesting applications of **dd**.

Example 15-58. Securely deleting a file

```
1 #!/bin/bash
2 # blot-out.sh: Erase "all" traces of a file.
3
4 # This script overwrites a target file alternately
```

```
5 #+ with random bytes, then zeros before finally deleting it.
 6 # After that, even examining the raw disk sectors by conventional methods
 7 #+ will not reveal the original file data.
9 PASSES=7
                 # Number of file-shredding passes.
1.0
                  # Increasing this slows script execution,
11
                  #+ especially on large target files.
12 BLOCKSIZE=1
                 # I/O with /dev/urandom requires unit block size,
13
                  #+ otherwise you get weird results.
                  # Various error exit codes.
14 E_BADARGS=70
15 E_NOT_FOUND=71
16 E_CHANGED_MIND=72
17
18 if [ -z "$1" ] # No filename specified.
19 then
   echo "Usage: `basename $0` filename"
21
   exit $E_BADARGS
22 fi
23
24 file=$1
25
26 if [ ! -e "$file" ]
27 then
28 echo "File \"$file\" not found."
29 exit $E_NOT_FOUND
30 fi
31
32 echo; echo -n "Are you absolutely sure you want to blot out \"$file\" (y/n)? "
33 read answer
34 case "$answer" in
35 [nN]) echo "Changed your mind, huh?"
36 exit $E_CHANGED_MIND
37
38 *)
        echo "Blotting out file \"$file\".";;
39 esac
40
41
42 flength=$(ls -1 "$file" | awk '{print $5}') # Field 5 is file length.
43 pass_count=1
44
45 chmod u+w "$file" # Allow overwriting/deleting the file.
46
47 echo
48
49 while [ "$pass_count" -le "$PASSES" ]
50 do
51 echo "Pass #$pass_count"
52 sync # Flush buffers.
dd if=/dev/urandom of=$file bs=$BLOCKSIZE count=$flength
54
                 # Fill with random bytes.
55 sync
                 # Flush buffers again.
dd if=/dev/zero of=$file bs=$BLOCKSIZE count=$flength
57
                 # Fill with zeros.
58 sync
                 # Flush buffers yet again.
59 let "pass_count += 1"
60 echo
61 done
62
63
64 rm -f $file  # Finally, delete scrambled and shredded file.
                 # Flush buffers a final time.
65 sync
66
67 echo "File \"$file\" blotted out and deleted."; echo
68
69
70 exit 0
```

```
71
72 # This is a fairly secure, if inefficient and slow method
73 #+ of thoroughly "shredding" a file.
74 # The "shred" command, part of the GNU "fileutils" package,
75 #+ does the same thing, although more efficiently.
77 # The file cannot not be "undeleted" or retrieved by normal methods.
78 # However . . .
79 #+ this simple method would *not* likely withstand
80 #+ sophisticated forensic analysis.
82 # This script may not play well with a journaled file system.
83 # Exercise (difficult): Fix it so it does.
85
87 # Tom Vier's "wipe" file-deletion package does a much more thorough job
88 #+ of file shredding than this simple script.
89 # http://www.ibiblio.org/pub/Linux/utils/file/wipe-2.0.0.tar.bz2
91 # For an in-depth analysis on the topic of file deletion and security,
92 #+ see Peter Gutmann's paper,
93 #+ "Secure Deletion of Data From Magnetic and Solid-State Memory".
       http://www.cs.auckland.ac.nz/~pgut001/pubs/secure_del.html
94 #
```

See also the <u>dd thread</u> entry in the <u>bibliography</u>.

od

The **od**, or *octal dump* filter converts input (or files) to octal (base-8) or other bases. This is useful for viewing or processing binary data files or otherwise unreadable system device files, such as /dev/urandom, and as a filter for binary data.

```
1 head -c4 /dev/urandom | od -N4 -tu4 | sed -ne 'ls/.* //p'
2 # Sample output: 1324725719, 3918166450, 2989231420, etc.
3
4 # From rnd.sh example script, by Stéphane Chazelas
```

See also Example 9-31 and Example A-38.

hexdump

Performs a hexadecimal, octal, decimal, or ASCII dump of a binary file. This command is the rough equivalent of **od**, above, but not nearly as useful. May be used to view the contents of a binary file, in combination with <u>dd</u> and <u>less</u>.

```
1 dd if=/bin/ls | hexdump -C | less
2 # The -C option nicely formats the output in tabular form.
```

objdump

Displays information about an object file or binary executable in either hexadecimal form or as a disassembled listing (with the -d option).

```
bash$ objdump -d /bin/ls
/bin/ls: file format elf32-i386

Disassembly of section .init:

080490bc <.init>:
80490bc: 55 push %ebp
80490bd: 89 e5 mov %esp,%ebp
. . .
```

mcookie

This command generates a "magic cookie," a 128-bit (32-character) pseudorandom hexadecimal number, normally used as an authorization "signature" by the X server. This also available for use in a

script as a "quick 'n dirty" random number.

```
1 random000=$(mcookie)
```

Of course, a script could use md5 for the same purpose.

```
1 # Generate md5 checksum on the script itself.
2 random001=`md5sum $0 | awk '{print $1}'`
3 # Uses 'awk' to strip off the filename.
```

The **mcookie** command gives yet another way to generate a "unique" filename.

Example 15-59. Filename generator

```
1 #!/bin/bash
 2 # tempfile-name.sh: temp filename generator
 4 BASE_STR=`mcookie` # 32-character magic cookie.
 5 POS=11
                      # Arbitrary position in magic cookie string.
 6 LEN=5
                       # Get $LEN consecutive characters.
 7
                       # This is, after all, a "temp" file.
 8 prefix=temp
                        # For more "uniqueness," generate the
 9
10
                        #+ filename prefix using the same method
11
                        #+ as the suffix, below.
12
13 suffix=${BASE_STR:POS:LEN}
14
                        # Extract a 5-character string,
15
                        #+ starting at position 11.
16
17 temp_filename=$prefix.$suffix
18
                       # Construct the filename.
19
20 echo "Temp filename = "$temp_filename""
21
22 # sh tempfile-name.sh
23 # Temp filename = temp.e19ea
25 # Compare this method of generating "unique" filenames
26 #+ with the 'date' method in ex51.sh.
27
28 exit 0
```

units

This utility converts between different *units of measure*. While normally invoked in interactive mode, **units** may find use in a script.

Example 15-60. Converting meters to miles

```
1 #!/bin/bash
2 # unit-conversion.sh
3
4
5 convert_units () # Takes as arguments the units to convert.
6 {
7   cf=$(units "$1" "$2" | sed --silent -e 'lp' | awk '{print $2}')
8   # Strip off everything except the actual conversion factor.
9   echo "$cf"
10 }
11
12 Unit1=miles
```

```
13 Unit2=meters
14 cfactor=`convert_units $Unit1 $Unit2`
15 quantity=3.73
17 result=$(echo $quantity*$cfactor | bc)
19 echo "There are $result $Unit2 in $quantity $Unit1."
20
21 # What happens if you pass incompatible units,
22 #+ such as "acres" and "miles" to the function?
23
24 exit 0
```

m4

A hidden treasure, **m4** is a powerful macro processing filter, [5] virtually a complete language. Although originally written as a pre-processor for *RatFor*, **m4** turned out to be useful as a stand-alone utility. In fact, m4 combines some of the functionality of eval, tr, and awk, in addition to its extensive macro expansion facilities.

The April, 2002 issue of *Linux Journal* has a very nice article on **m4** and its uses.

Example 15-61. Using *m4*

```
1 #!/bin/bash
 2 \ \text{# m4.sh:} Using the m4 macro processor
 4 # Strings
 5 string=abcdA01
 6 echo "len($string)" | m4
                                                            7
 7 echo "substr($string,4)" | m4
                                                          # A01
 8 echo "regexp(\$string,[0-1][0-1],\&Z)" | m4
                                                          # 01Z
10 # Arithmetic
11 echo "incr(22)" | m4
                                                             23
12 echo "eval(99 / 3)" | m4
                                                             33
13
14 exit 0
```

xmessage

This X-based variant of echo pops up a message/query window on the desktop.

```
1 xmessage Left click to continue -button okay
```

zenity

The <u>zenity</u> utility is adept at displaying *GTK*+ dialog <u>widgets</u> and <u>very suitable for scripting purposes</u>.

doexec

The **doexec** command enables passing an arbitrary list of arguments to a binary executable. In particular, passing arqv[0] (which corresponds to \$0 in a script) lets the executable be invoked by various names, and it can then carry out different sets of actions, according to the name by which it was called. What this amounts to is roundabout way of passing options to an executable.

For example, the /usr/local/bin directory might contain a binary called "aaa". Invoking doexec /usr/local/bin/aaa list would list all those files in the current working directory beginning with an "a", while invoking (the same executable with) **doexec /usr/local/bin/aaa delete** would *delete* those files.

The various behaviors of the executable must be defined within the code of the executable itself, analogous to something like the following in a shell script:

dialog

The <u>dialog</u> family of tools provide a method of calling interactive "dialog" boxes from a script. The more elaborate variations of **dialog** -- **gdialog**, **Xdialog**, and **kdialog** -- actually invoke X-Windows <u>widgets</u>.

SOX

The **sox**, or "**so**und **ex**change" command plays and performs transformations on sound files. In fact, the /usr/bin/play executable (now deprecated) is nothing but a shell wrapper for *sox*.

For example, **sox soundfile.wav soundfile.au** changes a WAV sound file into a (Sun audio format) AU sound file.

Shell scripts are ideally suited for batch-processing **sox** operations on sound files. For examples, see the <u>Linux Radio Timeshift HOWTO</u> and the <u>MP3do Project</u>.

Notes

- [1] This is actually a script adapted from the Debian Linux distribution.
- [2] The print queue is the group of jobs "waiting in line" to be printed.
- [3] For an excellent overview of this topic, see Andy Vaught's article, <u>Introduction to Named Pipes</u>, in the September, 1997 issue of *Linux Journal*.
- [4] EBCDIC (pronounced "ebb-sid-ick") is an acronym for Extended Binary Coded Decimal Interchange Code. This is an IBM data format no longer in much use. A bizarre application of the conv=ebcdic option of **dd** is as a quick 'n easy, but not very secure text file encoder.

```
1 cat $file | dd conv=swab,ebcdic > $file_encrypted
2 # Encode (looks like gibberish).
3 # Might as well switch bytes (swab), too, for a little extra obscurity.
4
5 cat $file_encrypted | dd conv=swab,ascii > $file_plaintext
6 # Decode.
```

[5] A *macro* is a symbolic constant that expands into a command string or a set of operations on parameters.

PrevHomeNextMath CommandsUpSystem and AdministrativeCommands

Advanced Bash-Scripting Guide: An in-depth exploration of the art of shell scripting

<u>Prev</u> <u>Next</u>

Chapter 16. System and Administrative Commands

The startup and shutdown scripts in /etc/rc.d illustrate the uses (and usefulness) of many of these comands. These are usually invoked by *root* and used for system maintenance or emergency filesystem repairs. Use with caution, as some of these commands may damage your system if misused.

Users and Groups

users

Show all logged on users. This is the approximate equivalent of **who -q**.

groups

Lists the current user and the groups she belongs to. This corresponds to the <u>\$GROUPS</u> internal variable, but gives the group names, rather than the numbers.

```
bash$ groups
bozita cdrom cdwriter audio xgrp
bash$ echo $GROUPS
501
```

chown, chgrp

The **chown** command changes the ownership of a file or files. This command is a useful method that *root* can use to shift file ownership from one user to another. An ordinary user may not change the ownership of files, not even her own files. [1]

```
root# chown bozo *.txt
```

The **chgrp** command changes the *group* ownership of a file or files. You must be owner of the file(s) as well as a member of the destination group (or *root*) to use this operation.

```
1 chgrp --recursive dunderheads *.data
2 # The "dunderheads" group will now own all the "*.data" files
3 #+ all the way down the $PWD directory tree (that's what "recursive" means).
```

useradd, userdel

The **useradd** administrative command adds a user account to the system and creates a home directory for that particular user, if so specified. The corresponding **userdel** command removes a user account from the system [2] and deletes associated files.

The **adduser** command is a synonym for **useradd** and is usually a symbolic link to it.

usermod

Modify a user account. Changes may be made to the password, group membership, expiration date, and other attributes of a given user's account. With this command, a user's password may be locked, which has the effect of disabling the account.

groupmod

Modify a given group. The group name and/or ID number may be changed using this command.

id

The **id** command lists the real and effective user IDs and the group IDs of the user associated with the current process. This is the counterpart to the <u>\$UID</u>, <u>\$EUID</u>, and <u>\$GROUPS</u> internal Bash variables.

```
bash$ id
  uid=501(bozo) gid=501(bozo) groups=501(bozo),22(cdrom),80(cdwriter),81(audio)
  bash$ echo $UID
  501
```

The **id** command shows the *effective* IDs only when they differ from the *real* ones.

Also see Example 9-5.

who

Show all users logged on to the system.

```
bash$ who
bozo tty1 Apr 27 17:45
bozo pts/0 Apr 27 17:46
 bozo pts/1 Apr 27 17:47
 bozo pts/2 Apr 27 17:49
```

The -m gives detailed information about only the current user. Passing any two arguments to **who** is the equivalent of who -m, as in who am i or who The Man.

```
bash$ who -m
localhost.localdomain!bozo pts/2 Apr 27 17:49
```

whoami is similar to **who -m**, but only lists the user name.

```
bash$ whoami
 bozo
```

W

Show all logged on users and the processes belonging to them. This is an extended version of **who**. The output of w may be piped to grep to find a specific user and/or process.

```
bash$ w | grep startx
                               4:22pm 6:41 4.47s 0.45s startx
bozo tty1
```

logname

Show current user's login name (as found in /var/run/utmp). This is a near-equivalent to whoami, above.

```
bash$ logname
bozo
 bash$ whoami
bozo
```

However . . .

```
bash$ su
Password: .....
bash# whoami
root
bash# logname
```

While **logname** prints the name of the logged in user, **whoami** gives the name of the user attached to the current process. As we have just seen, sometimes these are not the same.

su

Runs a program or script as a substitute user. su rjones starts a shell as user rjones. A naked su defaults to *root*. See Example A-15.

sudo

Runs a command as *root* (or another user). This may be used in a script, thus permitting a *regular* user to run the script.

```
1 #!/bin/bash
```

```
2
3 # Some commands.
4 sudo cp /root/secretfile /home/bozo/secret
5 # Some more commands.
```

The file /etc/sudoers holds the names of users permitted to invoke sudo.

passwd

Sets, changes, or manages a user's password.

The **passwd** command can be used in a script, but probably *should not* be.

Example 16-1. Setting a new password

```
1 #!/bin/bash
 2 # setnew-password.sh: For demonstration purposes only.
                         Not a good idea to actually run this script.
 4 # This script must be run as root.
                    # Root has $UID 0.
 6 ROOT UID=0
 7 E_WRONG_USER=65 # Not root?
9 E_NOSUCHUSER=70
10 SUCCESS=0
11
12
13 if [ "$UID" -ne "$ROOT_UID" ]
15 echo; echo "Only root can run this script."; echo
16
   exit $E_WRONG_USER
17 else
18
    echo
19 echo "You should know better than to run this script, root."
   echo "Even root users get the blues... "
2.0
21
    echo
22 fi
23
24
25 username=bozo
26 NEWPASSWORD=security_violation
27
28 # Check if bozo lives here.
29 grep -q "$username" /etc/passwd
30 if [ $? -ne $SUCCESS ]
31 then
32 echo "User $username does not exist."
33 echo "No password changed."
34 exit $E_NOSUCHUSER
35 fi
37 echo "$NEWPASSWORD" | passwd --stdin "$username"
38 # The '--stdin' option to 'passwd' permits
39 #+ getting a new password from stdin (or a pipe).
40
41 echo; echo "User $username's password changed!"
43 # Using the 'passwd' command in a script is dangerous.
44
45 exit 0
```

The **passwd** command's -1, -u, and -d options permit locking, unlocking, and deleting a user's password. Only *root* may use these options.

Show users' logged in time, as read from /var/log/wtmp. This is one of the GNU accounting utilities.

```
bash$ ac
      total
              68.08
```

last

List last logged in users, as read from /var/log/wtmp. This command can also show remote logins.

For example, to show the last few times the system rebooted:

```
bash$ last reboot
reboot system boot 2.6.9-1.667 Fri Feb 4 18:18 reboot system boot 2.6.9-1.667 Fri Feb 4 15:20 reboot system boot 2.6.9-1.667 Fri Feb 4 12:56
                                                                                         (00:02)
                                                                                         (01:27)
                                                                                         (00:49)
 reboot system boot 2.6.9-1.667
                                                    Thu Feb 3 21:08
                                                                                         (02:17)
 wtmp begins Tue Feb 1 12:50:09 2005
```

newgrp

Change user's group ID without logging out. This permits access to the new group's files. Since users may be members of multiple groups simultaneously, this command finds only limited use.

We will be a common or a contract the Example 1 When the little is a common of the contract that the Description of t the default group permissions for files a user writes. However, the chgrp command might be more convenient for this purpose.

Terminals

tty

Echoes the name of the current user's terminal. Note that each separate xterm window counts as a different terminal.

```
bash$ tty
/dev/pts/1
```

stty

Shows and/or changes terminal settings. This complex command, used in a script, can control terminal behavior and the way output displays. See the info page, and study it carefully.

Example 16-2. Setting an erase character

```
1 #!/bin/bash
 2 # erase.sh: Using "stty" to set an erase character when reading input.
 4 echo -n "What is your name? "
 5 read name
                                  # Try to backspace
 6
                                  #+ to erase characters of input.
 7
                                  # Problems?
 8 echo "Your name is $name."
10 stty erase '#'
                                  # Set "hashmark" (#) as erase character.
11 echo -n "What is your name? "
12 read name
                                 # Use # to erase last character typed.
13 echo "Your name is $name."
15 exit 0
16
```

```
17 # Even after the script exits, the new key value remains set.
18 # Exercise: How would you reset the erase character to the default value?
```

Example 16-3. secret password: Turning off terminal echoing

```
1 #!/bin/bash
 2 # secret-pw.sh: secret password
 4 echo
 5 echo -n "Enter password "
 6 read passwd
 7 echo "password is $passwd"
 8 echo -n "If someone had been looking over your shoulder, "
9 echo "your password would have been compromised."
10
11 echo && echo # Two line-feeds in an "and list."
12
13
14 stty -echo # Turns off screen echo.
15
16 echo -n "Enter password again "
17 read passwd
18 echo
19 echo "password is $passwd"
20 echo
21
22 stty echo # Restores screen echo.
2.3
24 exit 0
25
26 # Do an 'info stty' for more on this useful-but-tricky command.
```

A creative use of **stty** is detecting a user keypress (without hitting **ENTER**).

Example 16-4. Keypress detection

```
1 #!/bin/bash
 2 # keypress.sh: Detect a user keypress ("hot keys").
 4 echo
 6 old_tty_settings=$(stty -g) # Save old settings (why?).
 7 stty -icanon
 8 Keypress=$(head -c1)
                                # or $(dd bs=1 count=1 2> /dev/null)
                                 # on non-GNU systems
10
11 echo
12 echo "Key pressed was \""$Keypress"\"."
13 echo
14
15 stty "$old_tty_settings" # Restore old settings.
16
17 # Thanks, Stephane Chazelas.
19 exit 0
```

terminals and modes

Normally, a terminal works in the *canonical* mode. When a user hits a key, the resulting character does not immediately go to the program actually running in this terminal. A buffer local to the terminal stores keystrokes. When the user hits the **ENTER** key, this sends all the stored keystrokes to the program running. There is even a basic line editor inside the terminal.

```
bash$ stty -a
  speed 9600 baud; rows 36; columns 96; line = 0;
  intr = ^C; quit = ^\; erase = ^H; kill = ^U; eof = ^D; eol = <undef>; eol2 = <undef>;
  start = ^Q; stop = ^S; susp = ^Z; rprnt = ^R; werase = ^W; lnext = ^V; flush = ^O;
  ...
  isig icanon iexten echo echoe echok -echonl -noflsh -xcase -tostop -echoprt
```

Using canonical mode, it is possible to redefine the special keys for the local terminal line editor.

```
bash$ cat > filexxx
wha<ctl-W>I<ctl-H>foo bar<ctl-U>hello world<ENTER>
<ctl-D>
bash$ cat filexxx
hello world
bash$ wc -c < filexxx
12</pre>
```

The process controlling the terminal receives only 12 characters (11 alphabetic ones, plus a newline), although the user hit 26 keys.

In non-canonical ("raw") mode, every key hit (including special editing keys such as **ctl-H**) sends a character immediately to the controlling process.

The Bash prompt disables both icanon and echo, since it replaces the basic terminal line editor with its own more elaborate one. For example, when you hit **ctl-A** at the Bash prompt, there's no ^A echoed by the terminal, but Bash gets a \1 character, interprets it, and moves the cursor to the beginning of the line.

Stéphane Chazelas

setterm

Set certain terminal attributes. This command writes to its terminal's stdout a string that changes the behavior of that terminal.

```
bash$ setterm -cursor off
bash$
```

The **setterm** command can be used within a script to change the appearance of text written to stdout, although there are certainly <u>better tools</u> available for this purpose.

```
1 setterm -bold on
2 echo bold hello
3
4 setterm -bold off
5 echo normal hello
```

tset

Show or initialize terminal settings. This is a less capable version of stty.

```
bash$ tset -r
Terminal type is xterm-xfree86.
Kill is control-U (^U).
Interrupt is control-C (^C).
```

setserial

Set or display serial port parameters. This command must be run by *root* and is usually found in a system setup script.

```
1 # From /etc/pcmcia/serial script:
2
3 IRQ=`setserial /dev/$DEVICE | sed -e 's/.*IRQ: //'`
4 setserial /dev/$DEVICE irq 0; setserial /dev/$DEVICE irq $IRQ
```

getty, agetty

The initialization process for a terminal uses **getty** or **agetty** to set it up for login by a user. These commands are not used within user shell scripts. Their scripting counterpart is **stty**.

mesg

Enables or disables write access to the current user's terminal. Disabling access would prevent another user on the network to <u>write</u> to the terminal.

i It can be quite annoying to have a message about ordering pizza suddenly appear in the middle of the text file you are editing. On a multi-user network, you might therefore wish to disable write access to your terminal when you need to avoid interruptions.

wall

This is an acronym for "write all," i.e., sending a message to all users at every terminal logged into the network. It is primarily a system administrator's tool, useful, for example, when warning everyone that the system will shortly go down due to a problem (see Example 18-1).

```
bash$ wall System going down for maintenance in 5 minutes!

Broadcast message from bozo (pts/1) Sun Jul 8 13:53:27 2001...

System going down for maintenance in 5 minutes!
```

If write access to a particular terminal has been disabled with **mesg**, then **wall** cannot send a message to that terminal.

Information and Statistics

uname

Output system specifications (OS, kernel version, etc.) to stdout. Invoked with the -a option, gives verbose system info (see Example 15-5). The -s option shows only the OS type.

```
bash$ uname
Linux

bash$ uname -s
Linux

bash$ uname -a
Linux iron.bozo 2.6.15-1.2054_FC5 #1 Tue Mar 14 15:48:33 EST 2006
i686 i686 i386 GNU/Linux
```

arch

Show system architecture. Equivalent to **uname -m**. See Example 10-26.

```
bash$ arch
i686

bash$ uname -m
i686
```

lastcomm

Gives information about previous commands, as stored in the /var/account/pacct file. Command name and user name can be specified by options. This is one of the GNU accounting utilities.

lastlog

List the last login time of all system users. This references the /var/log/lastlog file.

```
bash$ lastlog
root tty1
                                    Fri Dec 7 18:43:21 -0700 2001
bin
                                     **Never logged in**
                                     **Never logged in**
daemon
                                     Sat Dec 8 21:14:29 -0700 2001
bozo
           tty1
bash$ lastlog | grep root
                                     Fri Dec 7 18:43:21 -0700 2001
 root
       tty1
```

1 This command will fail if the user invoking it does not have read permission for the /var/log/lastlog file.

lsof

List open files. This command outputs a detailed table of all currently open files and gives information about their owner, size, the processes associated with them, and more. Of course, lsof may be piped to grep and/or awk to parse and analyze its results.

bash\$ lsof								
COMMAND	PID	USER	FD	TYPE	DEVICE	SIZE	NODE	NAME
init	1	root	mem	REG	3,5	30748	30303	/sbin/init
init	1	root	mem	REG	3 , 5	73120	8069	/lib/ld-2.1.3.so
init	1	root	mem	REG	3 , 5	931668	8075	/lib/libc-2.1.3.so
cardmgr	213	root	mem	REG	3 , 5	36956	30357	/sbin/cardmgr

The **lsof** command is a useful, if complex administrative tool. If you are unable to dismount a filesystem and get an error message that it is still in use, then running *lsof* helps determine which files are still open on that filesystem. The -i option lists open network socket files, and this can help trace intrusion or hack attempts.

```
bash$ lsof -an -i tcp
 COMMAND PID USER FD TYPE DEVICE SIZE NODE NAME
 firefox 2330 bozo 32u IPv4 9956 TCP 66.0.118.137:57596->67.112.7.104:http ... firefox 2330 bozo 38u IPv4 10535 TCP 66.0.118.137:57708->216.79.48.24:http ...
```

strace

System trace: diagnostic and debugging tool for tracing system calls and signals. This command and **Itrace**, following, are useful for diagnosing why a given program or package fails to run . . . perhaps due to missing libraries or related causes.

```
bash$ strace df
 execve("/bin/df", ["df"], [/* 45 \text{ vars } */]) = 0
 uname({sys="Linux", node="bozo.localdomain", ...}) = 0
                                         = 0x804f5e4
```

This is the Linux equivalent of the Solaris **truss** command.

ltrace

Library trace: diagnostic and debugging tool that traces *library calls* invoked by a given command.

nmap

Network **map**per and port scanner. This command scans a server to locate open ports and the services associated with those ports. It can also report information about packet filters and firewalls. This is an important security tool for locking down a network against hacking attempts.

nc

The **nc** (*netcat*) utility is a complete toolkit for connecting to and listening to TCP and UDP ports. It is useful as a diagnostic and testing tool and as a component in simple script-based HTTP clients and servers.

```
bash$ nc localhost.localdomain 25
220 localhost.localdomain ESMTP Sendmail 8.13.1/8.13.1;
Thu, 31 Mar 2005 15:41:35 -0700
```

Example 16-5. Checking a remote server for *identd*

```
1 #! /bin/sh
 2 ## Duplicate DaveG's ident-scan thingie using netcat. Oooh, he'll be p*ssed.
 3 ## Args: target port [port port port ...]
 4 ## Hose stdout _and_ stderr together.
 5 ##
 6 ## Advantages: runs slower than ident-scan, giving remote inetd less cause
 7 ##+ for alarm, and only hits the few known daemon ports you specify.
 8 ## Disadvantages: requires numeric-only port args, the output sleazitude,
 9 ##+ and won't work for r-services when coming from high source ports.
10 # Script author: Hobbit <hobbit@avian.org>

58
59 # Notes:
60 #
62 # Try commenting out line 30 and running this script
63 #+ with "localhost.localdomain 25" as arguments.
65 # For more of Hobbit's 'nc' example scripts,
66 #+ look in the documentation:
67 #+ the /usr/share/doc/nc-X.XX/scripts directory.
```

And, of course, there's Dr. Andrew Tridgell's notorious one-line script in the BitKeeper Affair:

```
1 echo clone | nc thunk.org 5000 > e2fsprogs.dat
```

free

Shows memory and cache usage in tabular form. The output of this command lends itself to parsing, using grep, awk or **Perl**. The **procinfo** command shows all the information that **free** does, and much more.

```
bash$ free
             30504
              total
                        used
                                 free
                                         shared
                                                  buffers
                                                             cached
                                1880
                       28624
                                          15820
                                                   1608
                                                              16376
                              19864
  -/+ buffers/cache:
                       10640
                                65412
  Swap:
             68540
                        3128
```

To show unused RAM memory:

```
bash$ free | grep Mem | awk '{ print $4 }'
1880
```

procinfo

Extract and list information and statistics from the <u>/proc pseudo-filesystem</u>. This gives a very extensive and detailed listing.

```
bash$ procinfo | grep Bootup
Bootup: Wed Mar 21 15:15:50 2001 Load average: 0.04 0.21 0.34 3/47 6829
```

lsdev

List devices, that is, show installed hardware.

du

Show (disk) file usage, recursively. Defaults to current working directory, unless otherwise specified.

```
bash$ du -ach
1.0k    ./wi.sh
1.0k    ./tst.sh
1.0k    ./random.file
6.0k    .
6.0k    total
```

df

Shows filesystem usage in tabular form.

```
bash$ df
Filesystem 1k-blocks Used Available Use% Mounted on
/dev/hda5 273262 92607 166547 36% /
/dev/hda8 222525 123951 87085 59% /home
/dev/hda7 1408796 1075744 261488 80% /usr
```

dmesg

Lists all system bootup messages to stdout. Handy for debugging and ascertaining which device drivers were installed and which system interrupts in use. The output of **dmesg** may, of course, be parsed with grep, sed, or awk from within a script.

```
bash$ dmesg | grep hda
Kernel command line: ro root=/dev/hda2
hda: IBM-DLGA-23080, ATA DISK drive
hda: 6015744 sectors (3080 MB) w/96KiB Cache, CHS=746/128/63
hda: hda1 hda2 hda3 < hda5 hda6 hda7 > hda4
```

stat

Gives detailed and verbose statistics on a given file (even a directory or device file) or set of files.

If the target file does not exist, **stat** returns an error message.

```
bash$ stat nonexistent-file
nonexistent-file: No such file or directory
```

In a script, you can use **stat** to extract information about files (and filesystems) and set variables accordingly.

```
1 #!/bin/bash
 2 # fileinfo2.sh
 4 # Per suggestion of Joël Bourquard and . . .
 5 # http://www.linuxquestions.org/questions/showthread.php?t=410766
 8 FILENAME=testfile.txt
 9 file_name=$(stat -c%n "$FILENAME")  # Same as "$FILENAME" of course.
10 file_owner=$(stat -c%U "$FILENAME")
11 file_size=$(stat -c%s "$FILENAME")
12 # Certainly easier than using "ls -1 $FILENAME"
13 #+ and then parsing with sed.
14 file_inode=$(stat -c%i "$FILENAME")
15 file_type=$(stat -c%F "$FILENAME")
16 file_access_rights=$(stat -c%A "$FILENAME")
17
                         $file_name"
18 echo "File name:
19 echo "File owner:
                           $file_owner"
                           $file_size"
20 echo "File size:
21 echo "File inode:
                           $file_inode"
22 echo "File type: $file_type"
23 echo "File access rights: $file_access_rights"
25 exit 0
26
27 sh fileinfo2.sh
2.8
                 testfile.txt
bozo
29 File name:
30 File owner:
31 File size:
                      418
32 File inode: 1730378
33 File type: regular file
34 File access rights: -rw-rw-r--
```

vmstat

Display virtual memory statistics.

```
bash$ vmstat

procs memory swap io system cpu

r b w swpd free buff cache si so bi bo in cs us sy id

0 0 0 0 11040 2636 38952 0 0 33 7 271 88 8 3 89
```

netstat

Show current network statistics and information, such as routing tables and active connections. This utility accesses information in /proc/net (<u>Chapter 27</u>). See <u>Example 27-3</u>.

netstat -r is equivalent to <u>route</u>.

```
bash$ netstat

Active Internet connections (w/o servers)

Proto Recv-Q Send-Q Local Address Foreign Address State

Active UNIX domain sockets (w/o servers)

Proto RefCnt Flags Type State I-Node Path
unix 11 [] DGRAM 906 /dev/log
```

unix 3	[]	STREAM	CONNECTED	4514	/tmp/.X11-unix/X0
unix 3	[]	STREAM	CONNECTED	4513	

A **netstat -lptu** shows <u>sockets</u> that are listening to ports, and the associated processes. This can be useful for determining whether a computer has been hacked or compromised.

uptime

Shows how long the system has been running, along with associated statistics.

```
bash$ uptime
10:28pm up 1:57, 3 users, load average: 0.17, 0.34, 0.27
```

hostname

Lists the system's host name. This command sets the host name in an /etc/rc.d setup script (/etc/rc.d/rc.sysinit or similar). It is equivalent to **uname -n**, and a counterpart to the \$HOSTNAME internal variable.

```
bash$ hostname
localhost.localdomain

bash$ echo $HOSTNAME
localhost.localdomain
```

Similar to the **hostname** command are the **domainname**, **dnsdomainname**, **nisdomainname**, and **ypdomainname** commands. Use these to display or set the system DNS or NIS/YP domain name. Various options to **hostname** also perform these functions.

hostid

Echo a 32-bit hexadecimal numerical identifier for the host machine.

```
bash$ hostid 7f0100
```

This command allegedly fetches a "unique" serial number for a particular system. Certain product registration procedures use this number to brand a particular user license. Unfortunately, **hostid** only returns the machine network address in hexadecimal, with pairs of bytes transposed.

The network address of a typical non-networked Linux machine, is found in /etc/hosts.

```
bash$ cat /etc/hosts
127.0.0.1 localhost.localdomain localhost
```

As it happens, transposing the bytes of 127.0.0.1, we get 0.127.1.0, which translates in hex to 007f0100, the exact equivalent of what **hostid** returns, above. There exist only a few million other Linux machines with this identical *hostid*.

sar

Invoking **sar** (System Activity Reporter) gives a very detailed rundown on system statistics. The Santa Cruz Operation ("Old" SCO) released **sar** as Open Source in June, 1999.

This command is not part of the base Linux distribution, but may be obtained as part of the <u>sysstat utilities</u> package, written by <u>Sebastien Godard</u>.

```
bash$ sar
Linux 2.4.9 (brooks.seringas.fr) 09/26/03

10:30:00 CPU %user %nice %system %iowait %idle
```

10:40:00 10:50:00 11:00:00 Average:	all all all all	2.21 3.36 1.12 2.23	10.90 0.00 0.00 3.63	65.48 72.36 80.77 72.87	0.00 0.00 0.00 0.00	21.41 24.28 18.11 21.27

Average:	all	6.33	1.70	14.71	0.00	77.26

readelf

Show information and statistics about a designated *elf* binary. This is part of the *binutils* package.

```
bash$ readelf -h /bin/bash
ELF Header:
  Magic: 7f 45 4c 46 01 01 01 00 00 00 00 00 00 00 00
  Class:
                                     ELF32
  Data:
                                     2's complement, little endian
   Version:
                                     1 (current)
                                     UNIX - System V
   OS/ABI:
                                    Ω
  ABI Version:
                                    EXEC (Executable file)
  Type:
 . . .
```

size

The **size** [/path/to/binary] command gives the segment sizes of a binary executable or archive file. This is mainly of use to programmers.

```
bash$ size /bin/bash

text data bss dec hex filename

495971 22496 17392 535859 82d33 /bin/bash
```

System Logs

logger

Appends a user-generated message to the system log (/var/log/messages). You do not have to be *root* to invoke **logger**.

```
1 logger Experiencing instability in network connection at 23:10, 05/21.
2 # Now, do a 'tail /var/log/messages'.
```

By embedding a **logger** command in a script, it is possible to write debugging information to /var/log/messages.

```
1 logger -t $0 -i Logging at line "$LINENO".
2 # The "-t" option specifies the tag for the logger entry.
3 # The "-i" option records the process ID.
4
5 # tail /var/log/message
6 # ...
7 # Jul 7 20:48:58 localhost ./test.sh[1712]: Logging at line 3.
```

logrotate

This utility manages the system log files, rotating, compressing, deleting, and/or e-mailing them, as appropriate. This keeps the /var/log from getting cluttered with old log files. Usually <u>cron</u> runs **logrotate** on a daily basis.

Adding an appropriate entry to /etc/logrotate.conf makes it possible to manage personal log files, as well as system-wide ones.

Stefano Falsetto has created <u>rottlog</u>, which he considers to be an improved version of **logrotate**.

Job Control

ps

Process Statistics: lists currently executing processes by owner and PID (process ID). This is usually invoked with ax or aux options, and may be piped to grep or sed to search for a specific process (see Example 14-13 and Example 27-2).

```
bash$ ps ax | grep sendmail
295 ? S 0:00 sendmail: accepting connections on port 25
```

To display system processes in graphical "tree" format: **ps afjx** or **ps ax --forest**.

pgrep, pkill

Combining the **ps** command with grep or kill.

Compare the action of **pkill** with <u>killall</u>.

pstree

Lists currently executing processes in "tree" format. The -p option shows the PIDs, as well as the process names.

top

Continuously updated display of most cpu-intensive processes. The -b option displays in text mode, so that the output may be parsed or accessed from a script.

```
bash$ top -b
8:30pm up 3 min, 3 users, load average: 0.49, 0.32, 0.13
45 processes: 44 sleeping, 1 running, 0 zombie, 0 stopped
CPU states: 13.6% user, 7.3% system, 0.0% nice, 78.9% idle
Mem: 78396K av, 65468K used, 12928K free, 0K shrd, 2352K buff
Swap: 157208K av, 0K used, 157208K free 37244K cached

PID USER PRI NI SIZE RSS SHARE STAT %CPU %MEM TIME COMMAND
848 bozo 17 0 996 996 800 R 5.6 1.2 0:00 top
1 root 8 0 512 512 444 S 0.0 0.6 0:04 init
2 root 9 0 0 0 0 SW 0.0 0.0 0:00 keventd
...
```

nice

Run a background job with an altered priority. Priorities run from 19 (lowest) to -20 (highest). Only *root* may set the negative (higher) priorities. Related commands are **renice** and **snice**, which change the priority of a running process or processes, and **skill**, which sends a <u>kill</u> signal to a process or processes.

nohup

Keeps a command running even after user logs off. The command will run as a foreground process unless followed by &. If you use **nohup** within a script, consider coupling it with a <u>wait</u> to avoid creating an *orphan* or <u>zombie</u> process.

pidof

Identifies *process ID (PID)* of a running job. Since job control commands, such as <u>kill</u> and <u>renice</u> act on the *PID* of a process (not its name), it is sometimes necessary to identify that *PID*. The **pidof** command is the approximate counterpart to the <u>\$PPID</u> internal variable.

```
bash$ pidof xclock
880
```

Example 16-6. pidof helps kill a process

```
1 #!/bin/bash
 2 # kill-process.sh
 4 NOPROCESS=2
 6 process=xxxyyyzzz # Use nonexistent process.
 7 # For demo purposes only...
 8 # ... don't want to actually kill any actual process with this script.
10 # If, for example, you wanted to use this script to logoff the Internet,
11 # process=pppd
12
13 t=`pidof $process`
                          # Find pid (process id) of $process.
14 # The pid is needed by 'kill' (can't 'kill' by program name).
16 if [ -z "$t" ]
                           # If process not present, 'pidof' returns null.
17 then
   echo "Process $process was not running."
18
   echo "Nothing killed."
19
20 exit $NOPROCESS
21 fi
22
23 kill $t
                           # May need 'kill -9' for stubborn process.
25 # Need a check here to see if process allowed itself to be killed.
26 # Perhaps another " t=`pidof $process` " or ...
2.7
29 # This entire script could be replaced by
30 # kill $(pidof -x process_name)
31 # or
           killall process_name
33 # but it would not be as instructive.
35 exit 0
```

fuser

Identifies the processes (by PID) that are accessing a given file, set of files, or directory. May also be invoked with the -k option, which kills those processes. This has interesting implications for system security, especially in scripts preventing unauthorized users from accessing system services.

```
bash$ fuser -u /usr/bin/vim /usr/bin/vim: 3207e(bozo)
```

```
bash$ fuser -u /dev/null
/dev/null: 3009(bozo) 3010(bozo) 3197(bozo) 3199(bozo)
```

One important application for **fuser** is when physically inserting or removing storage media, such as CD ROM disks or USB flash drives. Sometimes trying a <u>umount</u> fails with a device is busy error message. This means that some user(s) and/or process(es) are accessing the device. An **fuser -um** /dev/device_name will clear up the mystery, so you can kill any relevant processes.

```
bash$ umount /mnt/usbdrive
umount: /mnt/usbdrive: device is busy

bash$ fuser -um /dev/usbdrive
/mnt/usbdrive: 1772c(bozo)

bash$ kill -9 1772
bash$ umount /mnt/usbdrive
```

The **fuser** command, invoked with the -n option identifies the processes accessing a *port*. This is especially useful in combination with <u>nmap</u>.

cron

Administrative program scheduler, performing such duties as cleaning up and deleting system log files and updating the slocate database. This is the superuser version of <u>at</u> (although each user may have their own crontab file which can be changed with the **crontab** command). It runs as a <u>daemon</u> and executes scheduled entries from /etc/crontab.

Some flavors of Linux run **crond**, Matthew Dillon's version of **cron**.

Process Control and Booting

init

The **init** command is the <u>parent</u> of all processes. Called in the final step of a bootup, **init** determines the runlevel of the system from /etc/inittab. Invoked by its alias **telinit**, and by *root* only.

telinit

Symlinked to **init**, this is a means of changing the system runlevel, usually done for system maintenance or emergency filesystem repairs. Invoked only by *root*. This command can be dangerous -- be certain you understand it well before using!

runlevel

Shows the current and last runlevel, that is, whether the system is halted (runlevel 0), in single-user mode (1), in multi-user mode (2 or 3), in X Windows (5), or rebooting (6). This command accesses the /var/run/utmp file.

halt, shutdown, reboot

Command set to shut the system down, usually just prior to a power down.

service

Starts or stops a system *service*. The startup scripts in /etc/init.d and /etc/rc.d use this command to start services at bootup.

```
root# /sbin/service iptables stop

Flushing firewall rules: [ OK ]

Setting chains to policy ACCEPT: filter [ OK ]

Unloading iptables modules: [ OK ]
```

Network

ifconfig

Network interface configuration and tuning utility.

The **ifconfig** command is most often used at bootup to set up the interfaces, or to shut them down when rebooting.

```
1 # Code snippets from /etc/rc.d/init.d/network
 2
 3 # ...
 4
 5 # Check that networking is up.
 6 [ ${NETWORKING} = "no" ] && exit 0
 8 [ -x /sbin/ifconfig ] || exit 0
9
10 # ...
11
12 for i in $interfaces; do
13 if ifconfig $i 2>/dev/null | grep -q "UP" >/dev/null 2>&1; then
14
     action "Shutting down interface $i: " ./ifdown $i boot
15 fi
16 # The GNU-specific "-q" option to "grep" means "quiet", i.e.,
17 #+ producing no output.
18 # Redirecting output to /dev/null is therefore not strictly necessary.
19
20 # ...
21
22 echo "Currently active devices:"
23 echo `/sbin/ifconfig | grep ^[a-z] | awk '{print $1}'`
                               ^^^^ should be quoted to prevent globbing.
25 # The following also work.
26 # echo (/sbin/ifconfig | awk '/^[a-z]/ { print $1 })'
      echo $(/sbin/ifconfig | sed -e 's/ .*//')
28 # Thanks, S.C., for additional comments.
```

See also Example 29-6.

iwconfig

This is the command set for configuring a wireless network. It is the wireless equivalent of **ifconfig**, above.

General purpose utility for setting up, changing, and analyzing *IP* (Internet Protocol) networks and attached devices. This command is part of the *iproute2* package.

```
bash$ ip link show
1: lo: <LOOPBACK,UP> mtu 16436 qdisc noqueue
    link/loopback 00:00:00:00:00 brd 00:00:00:00:00
2: eth0: <BROADCAST,MULTICAST> mtu 1500 qdisc pfifo_fast qlen 1000
    link/ether 00:d0:59:ce:af:da brd ff:ff:ff:ff:ff
3: sit0: <NOARP> mtu 1480 qdisc noop
    link/sit 0.0.0.0 brd 0.0.0.0
bash$ ip route list
169.254.0.0/16 dev lo scope link
```

Or, in a script:

```
1 #!/bin/bash
  2 # Script by Juan Nicolas Ruiz
  3 # Used with his kind permission.
  5 # Setting up (and stopping) a GRE tunnel.
  7
  8 # --- start-tunnel.sh ---
 10 LOCAL_IP="192.168.1.17"
 11 REMOTE_IP="10.0.5.33"
 12 OTHER_IFACE="192.168.0.100"
 13 REMOTE_NET="192.168.3.0/24"
 14
 15 /sbin/ip tunnel add netb mode gre remote $REMOTE_IP \
 16 local $LOCAL IP ttl 255
 17 /sbin/ip addr add $OTHER_IFACE dev netb
 18 /sbin/ip link set netb up
 19 /sbin/ip route add $REMOTE_NET dev netb
 2.0
 21 exit 0 ###########
 22
 23 # --- stop-tunnel.sh ---
 24
 25 REMOTE_NET="192.168.3.0/24"
 27 /sbin/ip route del $REMOTE_NET dev netb
 28 /sbin/ip link set netb down
 29 /sbin/ip tunnel del netb
 30
31 exit 0
```

route

Show info about or make changes to the kernel routing table.

```
      bash$ route

      Destination
      Gateway
      Genmask
      Flags
      MSS Window
      irtt Iface

      pm3-67.bozosisp
      *
      255.255.255.255 UH
      40 0
      0 ppp0

```

chkconfig

Check network and system configuration. This command lists and manages the network and system services started at bootup in the /etc/rc?.d directory.

Originally a port from IRIX to Red Hat Linux, **chkconfig** may not be part of the core installation of some Linux flavors.

```
bash$ chkconfig --list

atd 0:off 1:off 2:off 3:on 4:on 5:on 6:off
rwhod 0:off 1:off 2:off 3:off 4:off 5:off 6:off
...
```

tcpdump

Network packet "sniffer." This is a tool for analyzing and troubleshooting traffic on a network by dumping packet headers that match specified criteria.

Dump ip packet traffic between hosts bozoville and caduceus:

```
bash$ tcpdump ip host bozoville and caduceus
```

Of course, the output of **tcpdump** can be parsed with certain of the previously discussed <u>text</u> <u>processing utilities</u>.

Filesystem

mount

Mount a filesystem, usually on an external device, such as a floppy or CDROM. The file /etc/fstab provides a handy listing of available filesystems, partitions, and devices, including options, that may be automatically or manually mounted. The file /etc/mtab shows the currently mounted filesystems and partitions (including the virtual ones, such as /proc).

mount -a mounts all filesystems and partitions listed in /etc/fstab, except those with a noauto option. At bootup, a startup script in /etc/rc.d (rc.sysinit or something similar) invokes this to get everything mounted.

```
1 mount -t iso9660 /dev/cdrom /mnt/cdrom
2 # Mounts CD ROM. ISO 9660 is a standard CD ROM filesystem.
3 mount /mnt/cdrom
4 # Shortcut, if /mnt/cdrom listed in /etc/fstab
```

The versatile *mount* command can even mount an ordinary file on a block device, and the file will act as if it were a filesystem. *Mount* accomplishes that by associating the file with a <u>loopback device</u>. One application of this is to mount and examine an ISO9660 filesystem image before burning it onto a CDR. [3]

Example 16-7. Checking a CD image

```
1 # As root...
2
3 mkdir /mnt/cdtest # Prepare a mount point, if not already there.
4
5 mount -r -t iso9660 -o loop cd-image.iso /mnt/cdtest # Mount the image.
6 # "-o loop" option equivalent to "losetup /dev/loop0"
7 cd /mnt/cdtest # Now, check the image.
8 ls -alR # List the files in the directory tree there.
9 # And so forth.
```

umount

Unmount a currently mounted filesystem. Before physically removing a previously mounted floppy or CDROM disk, the device must be **umount**ed, else filesystem corruption may result.

```
1 umount /mnt/cdrom
2 # You may now press the eject button and safely remove the disk.
```

The **automount** utility, if properly installed, can mount and unmount floppies or CDROM disks as they are accessed or removed. On "multispindle" laptops with swappable floppy and optical drives, this can cause problems, however.

gnome-mount

The newer Linux distros have deprecated **mount** and **umount**. The successor, for command-line mounting of removable storage devices, is **gnome-mount**. It can take the -d option to mount a device file by its listing in /dev.

For example, to mount a USB flash drive:

```
bash$ gnome-mount -d /dev/sda1
gnome-mount 0.4

bash$ df
...
/dev/sda1 63584 12034 51550 19% /media/disk
```

sync

Forces an immediate write of all updated data from buffers to hard drive (synchronize drive with buffers). While not strictly necessary, a **sync** assures the sys admin or user that the data just changed will survive a sudden power failure. In the olden days, a **sync**; **sync** (twice, just to make absolutely sure) was a useful precautionary measure before a system reboot.

At times, you may wish to force an immediate buffer flush, as when securely deleting a file (see Example 15-58) or when the lights begin to flicker.

losetup

Sets up and configures <u>loopback devices</u>.

Example 16-8. Creating a filesystem in a file

```
1 SIZE=1000000 # 1 meg
2
3 head -c $SIZE < /dev/zero > file # Set up file of designated size.
4 losetup /dev/loop0 file # Set it up as loopback device.
5 mke2fs /dev/loop0 # Create filesystem.
6 mount -o loop /dev/loop0 /mnt # Mount it.
7
8 # Thanks, S.C.
```

mkswap

Creates a swap partition or file. The swap area must subsequently be enabled with **swapon**.

swapon, swapoff

Enable / disable swap partitition or file. These commands usually take effect at bootup and shutdown.

mke2fs

Create a Linux *ext2* filesystem. This command must be invoked as *root*.

Example 16-9. Adding a new hard drive

```
1 #!/bin/bash
2
3 # Adding a second hard drive to system.
4 # Software configuration. Assumes hardware already mounted.
```

```
5 # From an article by the author of this document.
 6 # In issue #38 of "Linux Gazette", http://www.linuxgazette.com.
8 ROOT_UID=0  # This script must be run as root.
9 E_NOTROOT=67 # Non-root exit error.
11 if [ "$UID" -ne "$ROOT_UID" ]
12 then
13 echo "Must be root to run this script."
14 exit $E_NOTROOT
15 fi
16
17 # Use with extreme caution!
18 # If something goes wrong, you may wipe out your current filesystem.
19
21 NEWDISK=/dev/hdb # Assumes /dev/hdb vacant. Check!
22 MOUNTPOINT=/mnt/newdisk # Or choose another mount point.
2.4
25 fdisk $NEWDISK
26 mke2fs -cv $NEWDISK1  # Check for bad blocks & verbose output.
27 # Note: /dev/hdb1, *not* /dev/hdb!
28 mkdir $MOUNTPOINT
29 chmod 777 $MOUNTPOINT # Makes new drive accessible to all users.
30
31
32 # Now, test...
33 # mount -t ext2 /dev/hdb1 /mnt/newdisk
34 # Try creating a directory.
35 # If it works, umount it, and proceed.
36
37 # Final step:
38 # Add the following line to /etc/fstab.
39 # /dev/hdb1 /mnt/newdisk ext2 defaults 1 1
40
41 exit 0
```

See also Example 16-8 and Example 28-3.

tune2fs

Tune *ext2* filesystem. May be used to change filesystem parameters, such as maximum mount count. This must be invoked as *root*.

This is an extremely dangerous command. Use it at your own risk, as you may inadvertently destroy your filesystem.

dumpe2fs

Dump (list to stdout) very verbose filesystem info. This must be invoked as root.

```
root# dumpe2fs /dev/hda7 | grep 'ount count'
dumpe2fs 1.19, 13-Jul-2000 for EXT2 FS 0.5b, 95/08/09
Mount count: 6
Maximum mount count: 20
```

hdparm

List or change hard disk parameters. This command must be invoked as *root*, and it may be dangerous if misused.

fdisk

Create or change a partition table on a storage device, usually a hard drive. This command must be invoked as *root*.

Use this command with extreme caution. If something goes wrong, you may destroy

an existing filesystem.

fsck, e2fsck, debugfs

Filesystem check, repair, and debug command set.

fsck: a front end for checking a UNIX filesystem (may invoke other utilities). The actual filesystem type generally defaults to ext2.

e2fsck: ext2 filesystem checker.

debugfs: ext2 filesystem debugger. One of the uses of this versatile, but dangerous command is to (attempt to) recover deleted files. For advanced users only!

1 All of these should be invoked as root, and they can damage or destroy a filesystem if misused.

badblocks

Checks for bad blocks (physical media flaws) on a storage device. This command finds use when formatting a newly installed hard drive or testing the integrity of backup media. [4] As an example, badblocks /dev/fd0 tests a floppy disk.

The badblocks command may be invoked destructively (overwrite all data) or in non-destructive read-only mode. If root user owns the device to be tested, as is generally the case, then root must invoke this command.

lsusb, usbmodules

The **Isusb** command lists all USB (Universal Serial Bus) buses and the devices hooked up to them.

The **usbmodules** command outputs information about the driver modules for connected USB devices.

```
bash$ lsusb
Bus 001 Device 001: ID 0000:0000
Device Descriptor:
  bLength
  bLength
bDescriptorType
                         1
  bcdUSB 1.00
bDeviceClass 9 Hub
  bDeviceSubClass
                         0
                    0
  bDeviceProtocol
  bMaxPacketSize0
  idVendor 0x0000 idProduct 0x0000
   . . .
```

lspci

Lists *pci* busses present.

```
bash$ lspci
00:00.0 Host bridge: Intel Corporation 82845 845
 (Brookdale) Chipset Host Bridge (rev 04)
00:01.0 PCI bridge: Intel Corporation 82845 845
 (Brookdale) Chipset AGP Bridge (rev 04)
00:1d.0 USB Controller: Intel Corporation 82801CA/CAM USB (Hub #1) (rev 02)
00:1d.1 USB Controller: Intel Corporation 82801CA/CAM USB (Hub #2) (rev 02)
00:1d.2 USB Controller: Intel Corporation 82801CA/CAM USB (Hub #3) (rev 02)
 00:1e.0 PCI bridge: Intel Corporation 82801 Mobile PCI Bridge (rev 42)
   . . .
```

mkbootdisk

Creates a boot floppy which can be used to bring up the system if, for example, the MBR (master boot record) becomes corrupted. Of special interest is the --iso option, which uses **mkisofs** to create a bootable ISO9660 filesystem image suitable for burning a bootable CDR.

The **mkbootdisk** command is actually a Bash script, written by Erik Troan, in the /sbin directory. mkisofs

Creates an ISO9660 filesystem suitable for a CDR image.

chroot

CHange ROOT directory. Normally commands are fetched from \$\frac{\\$PATH}{\}, \text{ relative to } /, \text{ the default} root directory. This changes the root directory to a different one (and also changes the working directory to there). This is useful for security purposes, for instance when the system administrator wishes to restrict certain users, such as those telnetting in, to a secured portion of the filesystem (this is sometimes referred to as confining a guest user to a "chroot jail"). Note that after a chroot, the execution path for system binaries is no longer valid.

A chroot /opt would cause references to /usr/bin to be translated to /opt/usr/bin. Likewise, chroot /aaa/bbb /bin/ls would redirect future instances of ls to /aaa/bbb as the base directory, rather than / as is normally the case. An alias XX 'chroot /aaa/bbb ls' in a user's ~/.bashrc effectively restricts which portion of the filesystem she may run command "XX" on.

The **chroot** command is also handy when running from an emergency boot floppy (**chroot** to /dev/fd0), or as an option to lilo when recovering from a system crash. Other uses include installation from a different filesystem (an rpm option) or running a readonly filesystem from a CD ROM. Invoke only as *root*, and use with care.

1 It might be necessary to copy certain system files to a *chrooted* directory, since the normal \$PATH can no longer be relied upon.

lockfile

This utility is part of the **procmail** package (<u>www.procmail.org</u>). It creates a *lock file*, a *semaphore* [5] file that controls access to a file, device, or resource. The lock file serves as a flag that this particular file, device, or resource is in use by a process (it is "busy"), and this permits only restricted access (or no access) to other processes.

```
1 lockfile /home/bozo/lockfiles/$0.lock
2 # Creates a write-protected lockfile prefixed with the name of the script.
```

Lock files are used in such applications as protecting system mail folders from simultaneously being changed by multiple users, indicating that a modem port is being accessed, and showing that an instance of Netscape is using its cache. Scripts may check for the existence of a lock file created by a certain process to check if that process is running. Note that if a script attempts to create a lock file that already exists, the script will likely hang.

Normally, applications create and check for lock files in the /var/lock directory. [6] A script can test for the presence of a lock file by something like the following.

```
1 appname=xyzip
2 # Application "xyzip" created lock file "/var/lock/xyzip.lock".
4 if [ -e "/var/lock/$appname.lock" ]
5 then #+ Prevent other programs & scripts
        # from accessing files/resources used by xyzip.
```

flock

Much less useful than the **lockfile** command is **flock**. It sets an "advisory" lock on a file and then executes a command while the lock is on. This is to prevent any other process from setting a lock on that file until completion of the specified command.

```
1 flock $0 cat $0 > lockfile__$0
2 # Set a lock on the script the above line appears in,
3 #+ while listing the script to stdout.
```

Tunlike lockfile, flock does not automatically create a lock file.

mknod

Creates block or character device files (may be necessary when installing new hardware on the system). The **MAKEDEV** utility has virtually all of the functionality of **mknod**, and is easier to use.

MAKEDEV

Utility for creating device files. It must be run as *root*, and in the /dev directory. It is a sort of advanced version of **mknod**.

tmpwatch

Automatically deletes files which have not been accessed within a specified period of time. Usually invoked by cron to remove stale log files.

Backup

dump, restore

The **dump** command is an elaborate filesystem backup utility, generally used on larger installations and networks. [7] It reads raw disk partitions and writes a backup file in a binary format. Files to be backed up may be saved to a variety of storage media, including disks and tape drives. The **restore** command restores backups made with **dump**.

fdformat

Perform a low-level format on a floppy disk (/dev/fd0*).

System Resources

ulimit

Sets an *upper limit* on use of system resources. Usually invoked with the -f option, which sets a limit on file size (**ulimit -f 1000** limits files to 1 meg maximum). The -t option limits the coredump size (**ulimit -c 0** eliminates coredumps). Normally, the value of **ulimit** would be set in /etc/profile and/or $\sim/.bash_profile$ (see Appendix G).

I Judicious use of **ulimit** can protect a system against the dreaded *fork bomb*.

A **ulimit -Hu XX** (where *XX* is the user process limit) in /etc/profile would abort this script when it exceeded the preset limit.

quota

Display user or group disk quotas.

setquota

Set user or group disk quotas from the command line.

umask

User file creation permissions *mask*. Limit the default file attributes for a particular user. All files created by that user take on the attributes specified by **umask**. The (octal) value passed to **umask** defines the file permissions *disabled*. For example, **umask 022** ensures that new files will have at

most 755 permissions (777 NAND 022). [8] Of course, the user may later change the attributes of particular files with <u>chmod</u>. The usual practice is to set the value of **umask** in /etc/profile and/or \sim /.bash_profile (see Appendix G).

Example 16-10. Using umask to hide an output file from prying eyes

```
1 #!/bin/bash
 2 # rot13a.sh: Same as "rot13.sh" script, but writes output to "secure" file.
 4 # Usage: ./rot13a.sh filename
 5 # or ./rot13a.sh <filename
 6 # or
         ./rot13a.sh and supply keyboard input (stdin)
7
 8 umask 177
                       # File creation mask.
                       # Files created by this script
10
                       #+ will have 600 permissions.
11
12 OUTFILE-decrypted.txt  # Results output to file "decrypted.txt"
                      #+ which can only be read/written
13
14
                       # by invoker of script (or root).
1.5
16 cat "$@" | tr 'a-zA-Z' 'n-za-mN-ZA-M' > $OUTFILE
19 exit 0
```

rdev

Get info about or make changes to root device, swap space, or video mode. The functionality of **rdev** has generally been taken over by **lilo**, but **rdev** remains useful for setting up a ram disk. This is a dangerous command, if misused.

Modules

lsmod

List installed kernel modules.

```
bash$ 1smod
Module
                   Size Used by
                    9456 2 (autoclean)
autofs
opl3
                   11376 0
serial_cs
                    5456 0 (unused)
                   34752 0
                    6384 0 [sb]
uart401
                  58368 0 [opl3 sb uart401]
sound
                     464 0 [sound]
soundlow
                    2800 6 [sb sound]
soundcore
                    6448 2 [serial_cs]
22928 2
as
i82365
pcmcia_core
                    45984 0 [serial_cs ds i82365]
```

Doing a cat /proc/modules gives the same information.

insmod

Force installation of a kernel module (use **modprobe** instead, when possible). Must be invoked as *root*.

rmmod

Force unloading of a kernel module. Must be invoked as *root*.

modprobe

Module loader that is normally invoked automatically in a startup script. Must be invoked as *root*.

depmod

Creates module dependency file. Usually invoked from a startup script.

modinfo

Output information about a loadable module.

```
bash$ modinfo hid
filename: /lib/modules/2.4.20-6/kernel/drivers/usb/hid.o
description: "USB HID support drivers"
author: "Andreas Gal, Vojtech Pavlik <vojtech@suse.cz>"
license: "GPL"
```

Miscellaneous

env

Runs a program or script with certain <u>environmental variables</u> set or changed (without changing the overall system environment). The [varname=xxx] permits changing the environmental variable varname for the duration of the script. With no options specified, this command lists all the environmental variable settings.

In Bash and other Bourne shell derivatives, it is possible to set variables in a single command's environment.

```
1 var1=value1 var2=value2 commandXXX
2 # $var1 and $var2 set in the environment of 'commandXXX' only.
```

The first line of a script (the "sha-bang" line) may use **env** when the path to the shell or interpreter is unknown.

```
1 #! /usr/bin/env perl
2
3 print "This Perl script will run,\n";
4 print "even when I don't know where to find Perl.\n";
5
6 # Good for portable cross-platform scripts,
7 # where the Perl binaries may not be in the expected place.
8 # Thanks, S.C.
```

ldd

Show shared lib dependencies for an executable file.

```
bash$ ldd /bin/ls
  libc.so.6 => /lib/libc.so.6 (0x4000c000)
/lib/ld-linux.so.2 => /lib/ld-linux.so.2 (0x80000000)
```

watch

Run a command repeatedly, at specified time intervals.

The default is two-second intervals, but this may be changed with the -n option.

```
1 watch -n 5 tail /var/log/messages
2 # Shows tail end of system log, /var/log/messages, every five seconds.
```

Tunfortunately, piping the output of watch command to grep does not work.

strip

Remove the debugging symbolic references from an executable binary. This decreases its size, but makes debugging it impossible.

This command often occurs in a Makefile, but rarely in a shell script.

List symbols in an unstripped compiled binary.

rdist

Remote distribution client: synchronizes, clones, or backs up a file system on a remote server.

16.1. Analyzing a System Script

Using our knowledge of administrative commands, let us examine a system script. One of the shortest and simplest to understand scripts is "killall," [9] used to suspend running processes at system shutdown.

Example 16-11. killall, from /etc/rc.d/init.d

```
1 #!/bin/sh
 3 # --> Comments added by the author of this document marked by "# -->".
 5 # --> This is part of the 'rc' script package
 6 # --> by Miquel van Smoorenburg, <miquels@drinkel.nl.mugnet.org>.
8 # --> This particular script seems to be Red Hat / FC specific
 9 \# --> (may not be present in other distributions).
11 # Bring down all unneeded services that are still running
12 #+ (there shouldn't be any, so this is just a sanity check)
14 for i in /var/lock/subsys/*; do
         # --> Standard for/in loop, but since "do" is on same line,
15
          # --> it is necessary to add ";".
          # Check if the script is there.
17
          [!-f $i ] && continue
          # --> This is a clever use of an "and list", equivalent to:
19
          # --> if [ ! -f "$i" ]; then continue
20
2.1
2.2
         # Get the subsystem name.
23
         subsys=${i#/var/lock/subsys/}
          # --> Match variable name, which, in this case, is the file name.
          # --> This is the exact equivalent of subsys=`basename $i`.
26
27
          # --> It gets it from the lock file name
          # -->+ (if there is a lock file,
29
          # -->+ that's proof the process has been running).
          # --> See the "lockfile" entry, above.
31
32
33
          # Bring the subsystem down.
3.4
          if [ -f /etc/rc.d/init.d/$subsys.init ]; then
35
             /etc/rc.d/init.d/$subsys.init stop
36
          else
37
             /etc/rc.d/init.d/$subsys stop
38
          # --> Suspend running jobs and daemons.
39
          # --> Note that "stop" is a positional parameter,
          # -->+ not a shell builtin.
41
          fi
42 done
```

That wasn't so bad. Aside from a little fancy footwork with variable matching, there is no new material there.

Exercise 1. In /etc/rc.d/init.d, analyze the **halt** script. It is a bit longer than **killall**, but similar in concept. Make a copy of this script somewhere in your home directory and experiment with it (do *not* run it as *root*). Do a simulated run with the -vn flags (**sh -vn scriptname**). Add extensive comments. Change the "action" commands to "echos".

Exercise 2. Look at some of the more complex scripts in /etc/rc.d/init.d. See if you can understand

parts of them. Follow the above procedure to analyze them. For some additional insight, you might also examine the file sysvinitfiles in /usr/share/doc/initscripts-?.??, which is part of the "initscripts" documentation.

Notes

- [1] This is the case on a Linux machine or a UNIX system with disk quotas.
- [2] The **userdel** command will fail if the particular user being deleted is still logged on.
- [3] For more detail on burning CDRs, see Alex Withers' article, <u>Creating CDs</u>, in the October, 1999 issue of *Linux Journal*.
- [4] The -c option to <u>mke2fs</u> also invokes a check for bad blocks.
- [5] Definition: A *semaphore* is a flag or signal. A UNIX process can check the appropriate semaphore to determine whether a particular resource is available/accessible.
- [6] Since only *root* has write permission in the /var/lock directory, a user script cannot set a lock file there.
- [7] Operators of single-user Linux systems generally prefer something simpler for backups, such as tar.
- [8] NAND is the logical *not-and* operator. Its effect is somewhat similar to subtraction.
- [9] The killall system script should not be confused with the killall command in /usr/bin.

Advanced Bash-Scripting Guide: An in-depth exploration of the art of shell scripting

<u>Prev</u> <u>Next</u>

Chapter 17. Regular Expressions

... the intellectual activity associated with software development is largely one of gaining insight.

--Stowe Boyd

To fully utilize the power of shell scripting, you need to master Regular Expressions. Certain commands and utilities commonly used in scripts, such as grep, expr, sed and awk, interpret and use REs. As of version 3, Bash has acquired its own RE-match operator: =~.

17.1. A Brief Introduction to Regular Expressions

An expression is a string of characters. Those characters having an interpretation above and beyond their literal meaning are called *metacharacters*. A quote symbol, for example, may denote speech by a person, *ditto*, or a meta-meaning [1] for the symbols that follow. Regular Expressions are sets of characters and/or metacharacters that match (or specify) patterns.

A Regular Expression contains one or more of the following:

- A character set. These are the characters retaining their literal meaning. The simplest type of Regular Expression consists *only* of a character set, with no metacharacters.
- An anchor. These designate (anchor) the position in the line of text that the RE is to match. For example, ^, and \$ are anchors.
- *Modifiers*. These expand or narrow (*modify*) the range of text the RE is to match. Modifiers include the asterisk, brackets, and the backslash.

The main uses for Regular Expressions (*RE*s) are text searches and string manipulation. An RE *matches* a single character or a set of characters -- a string or a part of a string.

• The asterisk -- * -- matches any number of repeats of the character string or RE preceding it, including *zero* instances.

```
"1133*" matches 11 + one or more 3's: 113, 1133, 1133333, and so forth.
```

• The dot -- . -- matches any one character, except a newline. [2]

```
"13." matches 13 + at least one of any character (including a space): 1133, 11333, but not 13 (additional character missing).
```

- The caret -- ^ -- matches the beginning of a line, but sometimes, depending on context, negates the meaning of a set of characters in an RE.
- The dollar sign -- \$ -- at the end of an RE matches the end of a line.

"XXX\$" matches XXX at the end of a line.

"^\$" matches blank lines.

Brackets -- [...] -- enclose a set of characters to match in a single RE.

"[xyz]" matches the characters x, y, or z.

"[c-n]" matches any of the characters in the range c to n.

"[B-Pk-y]" matches any of the characters in the ranges B to P and k to y.

"[a-z0-9]" matches any lowercase letter or any digit.

"[b -d]" matches all characters *except* those in the range b to d. This is an instance of n negating or inverting the meaning of the following RE (taking on a role similar to ! in a different context).

• The backslash -- \ -- escapes a special character, which means that character gets interpreted literally.

A "\\$" reverts back to its literal meaning of "\$", rather than its RE meaning of end-of-line. Likewise a "\\" has the literal meaning of "\".

Escaped "angle brackets" -- \<...\> -- mark word boundaries.

The angle brackets must be escaped, since otherwise they have only their literal character meaning.

"\<the\>" matches the word "the," but not the words "them," "there," "other," etc.

```
bash$ cat textfile
This is line 1, of which there is only one instance.
This is the only instance of line 2.
This is line 3, another line.
This is line 4.

bash$ grep 'the' textfile
This is line 1, of which there is only one instance.
This is the only instance of line 2.
This is line 3, another line.

bash$ grep '\<the\>' textfile
This is the only instance of line 2.
```

```
The only way to be certain that a particular RE works is to test it.
   1 TEST FILE: tstfile
                                                        # No match.
                                                        # No match.
   3 Run grep "1133*" on this file.
                                                        # Match.
                                                        # No match.
                                                        # No match.
   6 This line contains the number 113.
                                                       # Match.
                                                      # No match.
   7 This line contains the number 13.
                                                      # No match.
   8 This line contains the number 133.
                                                      # Match.
   9 This line contains the number 1133.
  10 This line contains the number 113312.
                                                      # Match.
  11 This line contains the number 1112.
                                                      # No match.
  12 This line contains the number 113312312. # Match.
  13 This line contains no numbers at all.
                                                      # No match.
bash$ grep "1133*" tstfile
 Run grep "1133*" on this file. # Match.
This line contains the number 113. # Match.
This line contains the number 1133. # Match.
This line contains the number 113312. # Match.
                                                  # Match.
 This line contains the number 113312312.
```

- Extended REs. Additional metacharacters added to the basic set. Used in egrep, awk, and Perl.
- The question mark -- ? -- matches zero or one of the previous RE. It is generally used for matching single characters.
- The plus -- + -- matches one or more of the previous RE. It serves a role similar to the *, but does *not* match zero occurrences.

```
1 # GNU versions of sed and awk can use "+",
2 # but it needs to be escaped.
3
4 echo alllb | sed -ne '/al\+b/p'
5 echo alllb | grep 'al\+b'
6 echo alllb | gawk '/al+b/'
7 # All of above are equivalent.
8
9 # Thanks, S.C.
```

• Escaped "curly brackets" -- \{ \} -- indicate the number of occurrences of a preceding RE to match.

It is necessary to escape the curly brackets since they have only their literal character meaning otherwise. This usage is technically not part of the basic RE set.

" $[0-9]\{5}$ " matches exactly five digits (characters in the range of 0 to 9).

Curly brackets are not available as an RE in the "classic" (non-POSIX compliant) version of <u>awk</u>. However, **gawk** has the --re-interval option that permits them (without being escaped).

```
bash$ echo 2222 | gawk --re-interval '/2{3}/'
2222
```

Perl and some **egrep** versions do not require escaping the curly brackets.

Parentheses -- () -- enclose a group of REs. They are useful with the following "I" operator and in <u>substring extraction</u> using <u>expr</u>.

• The -- I -- "or" RE operator matches any of a set of alternate characters.

```
bash$ egrep 're(a|e)d' misc.txt

People who read seem to be better informed than those who do not.

The clarinet produces sound by the vibration of its reed.
```

Some versions of **sed**, **ed**, and **ex** support escaped versions of the extended Regular Expressions described above, as do the GNU utilities.

• POSIX Character Classes. [:class:]

This is an alternate method of specifying a range of characters to match.

- [:alnum:] matches alphabetic or numeric characters. This is equivalent to A-Za-z0-9.
- [:alpha:] matches alphabetic characters. This is equivalent to A-Za-z.
- [:blank:] matches a space or a tab.
- [:cntrl:] matches control characters.
- [:digit:] matches (decimal) digits. This is equivalent to 0-9.
- [:graph:] (graphic printable characters). Matches characters in the range of ASCII 33 126. This is the same as [:print:], below, but excluding the space character.
- [:lower:] matches lowercase alphabetic characters. This is equivalent to a-z.
- [:print:] (printable characters). Matches characters in the range of ASCII 32 126. This is the same as [:graph:], above, but adding the space character.
- [:space:] matches whitespace characters (space and horizontal tab).
- [:upper:] matches uppercase alphabetic characters. This is equivalent to A-Z.
- [:xdigit:] matches hexadecimal digits. This is equivalent to 0-9A-Fa-f.
 - POSIX character classes generally require quoting or double brackets ([[]]).

```
bash$ grep [[:digit:]] test.file
abc=723
```

These character classes may even be used with globbing, to a limited extent.

```
bash$ ls -l ?[[:digit:]][[:digit:]]?
-rw-rw-r-- 1 bozo bozo 0 Aug 21 14:47 a33b
```

To see POSIX character classes used in scripts, refer to <u>Example 15-20</u> and <u>Example 15-21</u>.

<u>Sed</u>, <u>awk</u>, and <u>Perl</u>, used as filters in scripts, take REs as arguments when "sifting" or transforming files or I/O streams. See <u>Example A-12</u> and <u>Example A-17</u> for illustrations of this.

The standard reference on this complex topic is Friedl's *Mastering Regular Expressions*. *Sed & Awk*, by Dougherty and Robbins, also gives a very lucid treatment of REs. See the *Bibliography* for more information on these books.

Notes

Prev

- [1] A *meta-meaning* is the meaning of a term or expression on a higher level of abstraction. For example, the *literal* meaning of *regular expression* is an ordinary expression that conforms to accepted usage. The *meta-meaning* is drastically different, as discussed at length in this chapter.
- [2] Since <u>sed</u>, <u>awk</u>, and <u>grep</u> process single lines, there will usually not be a newline to match. In those cases where there is a newline in a multiple line expression, the dot will match the newline.

```
1 #!/bin/bash
 3 sed -e 'N;s/.*/[&]/' << EOF  # Here Document
 4 line1
 5 line2
 6 EOF
 7 # OUTPUT:
 8 # [line1
9 # line21
10
11
12
13 echo
14
15 awk '{ $0=$1 "\n" $2; if (/line.1/) {print}}' << EOF
16 line 1
17 line 2
18 EOF
19 # OUTPUT:
20 # line
21 # 1
22
23
24 # Thanks, S.C.
2.5
26 exit 0
```

Advanced Bash-Scripting Guide: An in-depth exploration of the art of shell scripting

17.2. Globbing

Bash itself cannot recognize Regular Expressions. Inside scripts, it is commands and utilities -- such as <u>sed</u> and <u>awk</u> -- that interpret RE's.

Bash *does* carry out *filename expansion* [1] -- a process known as *globbing* -- but this does *not* use the standard RE set. Instead, globbing recognizes and expands wildcards. Globbing interprets the standard wildcard characters, * and ?, character lists in square brackets, and certain other special characters (such as ^ for negating the sense of a match). There are important limitations on wildcard characters in globbing, however. Strings containing * will not match filenames that start with a dot, as, for example, .bashrc. [2] Likewise, the ? has a different meaning in globbing than as part of an RE.

Bash performs filename expansion on unquoted command-line arguments. The <u>echo</u> command demonstrates this.

```
bash$ echo *
a.1 b.1 c.1 t2.sh test1.txt

bash$ echo t*
t2.sh test1.txt
```

It is possible to modify the way Bash interprets special characters in globbing. A set -f command disables globbing, and the nocaseglob and nullglob options to shopt change globbing behavior. See also Example 10-4.

Notes

- [1] Filename expansion means expanding filename patterns or templates containing special characters. For example, example.??? might expand to example.001 and/or example.txt.
- [2] Filename expansion *can* match dotfiles, but only if the pattern explicitly includes the dot as a literal character.

```
1 ~/[.]bashrc # Will not expand to ~/.bashrc
2 ~/?bashrc # Neither will this.
3 # Wild cards and metacharacters will NOT
4 #+ expand to a dot in globbing.
5
6 ~/.[b]ashrc # Will expand to ~/.bashrc
7 ~/.ba?hrc # Likewise.
8 ~/.bashr* # Likewise.
9
10 # Setting the "dotglob" option turns this off.
11
12 # Thanks, S.C.
```

Regular Expressions Up Here Documents
Advanced Bash-Scripting Guide: An in-depth exploration of the art of shell scripting
Prev Next

Chapter 18. Here Documents

Here and now, boys.

--Aldous Huxley, **Island**

A *here document* is a special-purpose code block. It uses a form of <u>I/O redirection</u> to feed a command list to an interactive program or a command, such as <u>ftp</u>, <u>cat</u>, or the *ex* text editor.

```
1 COMMAND <<InputComesFromHERE
2 ...
3 InputComesFromHERE
```

A *limit string* delineates (frames) the command list. The special symbol << designates the limit string. This has the effect of redirecting the output of a file into the stdin of the program or command. It is similar to **interactive-program** < **command-file**, where command-file contains

```
1 command #1
2 command #2
3 ...
```

The here document alternative looks like this:

```
1 #!/bin/bash
2 interactive-program <<LimitString
3 command #1
4 command #2
5 ...
6 LimitString</pre>
```

Choose a *limit string* sufficiently unusual that it will not occur anywhere in the command list and confuse matters.

Note that *here documents* may sometimes be used to good effect with non-interactive utilities and commands, such as, for example, <u>wall</u>.

Example 18-1. *broadcast*: Sends message to everyone logged in

Even such unlikely candidates as the vi text editor lend themselves to here documents.

Example 18-2. dummyfile: Creates a 2-line dummy file

```
1 #!/bin/bash
3 # Non-interactive use of 'vi' to edit a file.
4 # Emulates 'sed'.
6 E_BADARGS=65
8 if [ -z "$1" ]
9 then
10 echo "Usage: `basename $0` filename"
11 exit $E_BADARGS
12 fi
13
14 TARGETFILE=$1
15
16 # Insert 2 lines in file, then save.
17 #-----#
18 vi $TARGETFILE <<x23LimitStringx23
19 i
20 This is line 1 of the example file.
21 This is line 2 of the example file.
22 ^[
23 ZZ
24 x23LimitStringx23
25 #-----#
27 # Note that ^[ above is a literal escape
28 #+ typed by Control-V <Esc>.
30 # Bram Moolenaar points out that this may not work with 'vim',
31 #+ because of possible problems with terminal interaction.
32
33 exit 0
```

The above script could just as effectively have been implemented with **ex**, rather than **vi**. Here documents containing a list of **ex** commands are common enough to form their own category, known as *ex scripts*.

```
1 #!/bin/bash
2 # Replace all instances of "Smith" with "Jones"
3 #+ in files with a ".txt" filename suffix.
5 ORIGINAL=Smith
6 REPLACEMENT=Jones
8 for word in $(fgrep -1 $ORIGINAL *.txt)
9 do
10 # -----
11 ex $word <<EOF
12 :%s/$ORIGINAL/$REPLACEMENT/g
13 :wq
14 EOF
# :%s is the "ex" substitution command.
16 # :wq is write-and-quit.
17
   # -----
18 done
```

Analogous to "ex scripts" are cat scripts.

Example 18-3. Multi-line message using cat

```
1 #!/bin/bash
3 # 'echo' is fine for printing single line messages,
4 #+ but somewhat problematic for for message blocks.
5 # A 'cat' here document overcomes this limitation.
7 cat <<End-of-message
9 This is line 1 of the message.
10 This is line 2 of the message.
11 This is line 3 of the message.
12 This is line 4 of the message.
13 This is the last line of the message.
15 End-of-message
17 # Replacing line 7, above, with
18 #+ cat > $Newfile <<End-of-message
19 #+ ^^^^^^
20 \#+ writes the output to the file Newfile, rather than to stdout.
22 exit 0
2.3
24
26 # Code below disabled, due to "exit 0" above.
28 # S.C. points out that the following also works.
29 echo "--
30 This is line 1 of the message.
31 This is line 2 of the message.
32 This is line 3 of the message.
33 This is line 4 of the message.
34 This is the last line of the message.
35 -----
36 # However, text may not include double quotes unless they are escaped.
```

The – option to mark a here document limit string (**<<-LimitString**) suppresses leading tabs (but not spaces) in the output. This may be useful in making a script more readable.

Example 18-4. Multi-line message, with tabs suppressed

```
1 #!/bin/bash
 2 # Same as previous example, but...
4 # The - option to a here document <<-
5 #+ suppresses leading tabs in the body of the document,
 6 #+ but *not* spaces.
8 cat <<-ENDOFMESSAGE
9 This is line 1 of the message.
10 This is line 2 of the message.
    This is line 3 of the message.
11
    This is line 4 of the message.
12
13
    This is the last line of the message.
14 ENDOFMESSAGE
15 # The output of the script will be flush left.
16 # Leading tab in each line will not show.
18 # Above 5 lines of "message" prefaced by a tab, not spaces.
19 # Spaces not affected by <<- .
20
```

```
21 # Note that this option has no effect on *embedded* tabs.
22
23 exit 0
```

A *here document* supports parameter and command substitution. It is therefore possible to pass different parameters to the body of the here document, changing its output accordingly.

Example 18-5. Here document with parameter substitution

```
1 #!/bin/bash
2 # Another 'cat' here document, using parameter substitution.
 4 # Try it with no command line parameters,
                                              ./scriptname
 5 # Try it with one command line parameter,
                                              ./scriptname Mortimer
 6 # Try it with one two-word quoted command line parameter,
                              ./scriptname "Mortimer Jones"
8
9 CMDLINEPARAM=1
                    # Expect at least command line parameter.
10
11 if [ $# -ge $CMDLINEPARAM ]
12 then
13 NAME=$1
                      # If more than one command line param,
14
                      #+ then just take the first.
15 else
16 NAME="John Doe" # Default, if no command line parameter.
17 fi
18
19 RESPONDENT="the author of this fine script"
20
21
22 cat <<Endofmessage
23
24 Hello, there, $NAME.
25 Greetings to you, $NAME, from $RESPONDENT.
27 # This comment shows up in the output (why?).
28
29 Endofmessage
30
31 # Note that the blank lines show up in the output.
32 # So does the "comment".
33
34 exit 0
```

This is a useful script containing a here document with parameter substitution.

Example 18-6. Upload a file pair to *Sunsite* incoming directory

```
1 #!/bin/bash
2 # upload.sh
3
4 # Upload file pair (Filename.lsm, Filename.tar.gz)
5 #+ to incoming directory at Sunsite/UNC (ibiblio.org).
6 # Filename.tar.gz is the tarball itself.
7 # Filename.lsm is the descriptor file.
8 # Sunsite requires "lsm" file, otherwise will bounce contributions.
9
```

```
10
11 E_ARGERROR=65
12
13 if [ -z "$1" ]
15 echo "Usage: `basename $0` Filename-to-upload"
16 exit $E_ARGERROR
17 fi
18
19
20 Filename=`basename $1` # Strips pathname out of file name.
22 Server="ibiblio.org"
23 Directory="/incoming/Linux"
24 # These need not be hard-coded into script,
25 #+ but may instead be changed to command line argument.
27 Password="your.e-mail.address" # Change above to suit.
28
29 ftp -n $Server <<End-Of-Session
30 # -n option disables auto-logon
32 user anonymous "$Password"
33 binary
34 bell
                                  # Ring 'bell' after each file transfer.
35 cd $Directory
36 put "$Filename.lsm"
37 put "$Filename.tar.gz"
38 bye
39 End-Of-Session
40
41 exit 0
```

Quoting or escaping the "limit string" at the head of a here document disables parameter substitution within its body.

Example 18-7. Parameter substitution turned off

```
1 #!/bin/bash
 2 # A 'cat' here-document, but with parameter substitution disabled.
 4 NAME="John Doe"
 5 RESPONDENT="the author of this fine script"
7 cat <<'Endofmessage'
9 Hello, there, $NAME.
10 Greetings to you, $NAME, from $RESPONDENT.
12 Endofmessage
13
14 \# No parameter substitution when the "limit string" is quoted or escaped.
15 # Either of the following at the head of the here document would have
16 #+ the same effect.
     cat <<"Endofmessage"
18 # cat <<\Endofmessage
19
20 exit 0
```

Disabling parameter substitution permits outputting literal text. Generating scripts or even program code is one use for this.

Example 18-8. A script that generates another script

```
1 #!/bin/bash
2 # generate-script.sh
3 # Based on an idea by Albert Reiner.
5 OUTFILE=generated.sh
                              # Name of the file to generate.
9 # 'Here document containing the body of the generated script.
10 (
11 cat <<'EOF'
12 #!/bin/bash
13
14 echo "This is a generated shell script."
15 # Note that since we are inside a subshell,
16 #+ we can't access variables in the "outside" script.
17
18 echo "Generated file will be named: $OUTFILE"
19 # Above line will not work as normally expected
20 #+ because parameter expansion has been disabled.
21 # Instead, the result is literal output.
22
23 a=7
24 b=3
25
26 let "c = $a * $b"
27 echo "c = $c"
28
29 exit 0
30 EOF
31 ) > $OUTFILE
32 # -
33
34 # Quoting the 'limit string' prevents variable expansion
35 #+ within the body of the above 'here document.'
36 # This permits outputting literal strings in the output file.
37
38 if [ -f "$OUTFILE" ]
39 then
40 chmod 755 $OUTFILE
41 # Make the generated file executable.
42 else
43 echo "Problem in creating file: \"$OUTFILE\""
44 fi
45
46 \# This method can also be used for generating
47 #+ C programs, Perl programs, Python programs, Makefiles,
48 #+ and the like.
49
50 exit 0
```

It is possible to set a variable from the output of a here document. This is actually a devious form of <u>command substitution</u>.

```
1 variable=$(cat <<SETVAR
2 This variable
```

```
3 runs over multiple lines.
4 SETVAR)
5
6 echo "$variable"
```

A here document can supply input to a function in the same script.

Example 18-9. Here documents and functions

```
1 #!/bin/bash
 2 # here-function.sh
 4 GetPersonalData ()
 5 {
 6 read firstname
 7
   read lastname
 8 read address
 9 read city
10 read state
11 read zipcode
12 } # This certainly looks like an interactive function, but...
13
15 # Supply input to the above function.
16 GetPersonalData <<RECORD001
17 Bozo
18 Bozeman
19 2726 Nondescript Dr.
20 Baltimore
21 MD
22 21226
23 RECORD001
24
25
26 echo
27 echo "$firstname $lastname"
28 echo "$address"
29 echo "$city, $state $zipcode"
30 echo
31
32 exit 0
```

It is possible to use: as a dummy command accepting output from a here document. This, in effect, creates an "anonymous" here document.

Example 18-10. "Anonymous" Here Document

```
1 #!/bin/bash
2
3 : <<TESTVARIABLES
4 ${HOSTNAME?}${USER?}${MAIL?} # Print error message if one of the variables not set.
5 TESTVARIABLES
6
7 exit 0</pre>
```

(i) A variation of the above technique permits "commenting out" blocks of code.

Example 18-11. Commenting out a block of code

```
1 #!/bin/bash
2 # commentblock.sh
4 : <<COMMENTBLOCK
5 echo "This line will not echo."
 6 This is a comment line missing the "#" prefix.
7 This is another comment line missing the "#" prefix.
9 & * @ ! ! + +=
10 The above line will cause no error message,
11 because the Bash interpreter will ignore it.
12 COMMENTBLOCK
13
14 echo "Exit value of above \"COMMENTBLOCK\" is $?." # 0
15 # No error shown.
16 echo
17
18
19 # The above technique also comes in useful for commenting out
20 #+ a block of working code for debugging purposes.
21 # This saves having to put a "#" at the beginning of each line,
22 #+ then having to go back and delete each "#" later.
24 echo "Just before commented-out code block."
25 # The lines of code between the double-dashed lines will not execute.
26 # -----
27 : <<DEBUGXXX
28 for file in *
29 do
30 cat "$file"
31 done
32 DEBUGXXX
34 echo "Just after commented-out code block."
35
36 exit 0
37
38
39
41 # Note, however, that if a bracketed variable is contained within
42 #+ the commented-out code block,
43 #+ then this could cause problems.
44 # for example:
45
46
47 #/!/bin/bash
48
49
   : <<COMMENTBLOCK
50 echo "This line will not echo."
51
    & *@!!++=
    ${foo_bar_bazz?}
53
   $(rm -rf /tmp/foobar/)
   $ (touch my_build_directory/cups/Makefile)
55 COMMENTBLOCK
56
57
58 $ sh commented-bad.sh
59 commented-bad.sh: line 3: foo_bar_bazz: parameter null or not set
60
61 # The remedy for this is to strong-quote the 'COMMENTBLOCK' in line 49, above.
```

```
62
63 : <<'COMMENTBLOCK'
64
65 # Thank you, Kurt Pfeifle, for pointing this out.
```

i Yet another twist of this nifty trick makes "self-documenting" scripts possible.

Example 18-12. A self-documenting script

```
1 #!/bin/bash
 2 # self-document.sh: self-documenting script
3 # Modification of "colm.sh".
5 DOC_REQUEST=70
 7 if [ "$1" = "-h" -o "$1" = "--help" ] # Request help.
   echo; echo "Usage: $0 [directory-name]"; echo
    sed --silent -e '/DOCUMENTATIONXX$/,/^DOCUMENTATIONXX$/p' "$0" |
10
11
   sed -e '/DOCUMENTATIONXX$/d'; exit $DOC_REQUEST; fi
12
13
14 : <<DOCUMENTATIONXX
15 List the statistics of a specified directory in tabular format.
17 The command line parameter gives the directory to be listed.
18 If no directory specified or directory specified cannot be read,
19 then list the current working directory.
21 DOCUMENTATIONXX
23 if [ -z "$1" -o ! -r "$1" ]
24 then
25 directory=.
26 else
27 directory="$1"
28 fi
29
30 echo "Listing of "$directory":"; echo
31 (printf "PERMISSIONS LINKS OWNER GROUP SIZE MONTH DAY HH:MM PROG-NAME\n" \
32 ; ls -1 "$directory" | sed 1d) | column -t
34 exit 0
```

Using a <u>cat script</u> is an alternate way of accomplishing this.

See also Example A-30 for one more excellent example of a self-documenting script.

Here documents create temporary files, but these files are deleted after opening and are not accessible to any other process.

- 1 Some utilities will not work inside a here document.
- The closing *limit string*, on the final line of a here document, must start in the *first* character position. There can be *no leading whitespace*. Trailing whitespace after the limit string likewise causes unexpected behavior. The whitespace prevents the limit string from being recognized.

```
1 #!/bin/bash
5 cat <<LimitString
6 echo "This is line 1 of the message inside the here document."
7 echo "This is line 2 of the message inside the here document."
8 echo "This is the final line of the message inside the here document."
9 LimitString
10 #^^^Indented limit string. Error! This script will not behave as expected.
11
12 echo "-----
13
14 # These comments are outside the 'here document',
15 #+ and should not echo.
17 echo "Outside the here document."
18
19 exit 0
21 echo "This line had better not echo." # Follows an 'exit' command.
```

For those tasks too complex for a "here document", consider using the **expect** scripting language, which is specifically tailored for feeding input into interactive programs.

18.1. Here Strings

A *here string* can be considered as a stripped-down form of a *here document*. It consists of nothing more than **COMMAND** << \$WORD, where \$WORD is expanded and fed to the stdin of COMMAND.

As a simple example, consider this alternative to the <u>echo-grep</u> construction.

```
1 # Instead of:
2 if echo "$VAR" | grep -q txt # if [[ $VAR = *txt* ]]
3 # etc.
4
5 # Try:
6 if grep -q "txt" <<< "$VAR"
7 then
8 echo "$VAR contains the substring sequence \"txt\""
9 fi
10 # Thank you, Sebastian Kaminski, for the suggestion.</pre>
```

Or, in combination with read:

```
1 String="This is a string of words."
 3 read -r -a Words <<< "$String"
 4 # The -a option to "read"
 5 #+ assigns the resulting values to successive members of an array.
 7 echo "First word in String is: ${Words[0]}"
                                                  # This
 8 echo "Second word in String is: ${Words[1]}"
                                                  # is
 9 echo "Third word in String is: ${Words[2]}"
10 echo "Fourth word in String is: ${Words[3]}"
                                                  # string
                                                  # of
11 echo "Fifth word in String is: ${Words[4]}"
12 echo "Sixth word in String is: ${Words[5]}"
                                                  # words.
13 echo "Seventh word in String is: ${Words[6]}"
                                                 # (null)
14
                                                   # Past end of $String.
16 # Thank you, Francisco Lobo, for the suggestion.
```

Example 18-13. Prepending a line to a file

```
1 #!/bin/bash
 2 # prepend.sh: Add text at beginning of file.
 4 # Example contributed by Kenny Stauffer,
 5 #+ and slightly modified by document author.
 7
 8 E_NOSUCHFILE=65
10 read -p "File: " file # -p arg to 'read' displays prompt.
11 if [ ! -e "$file" ]
12 then # Bail out if no such file.
   echo "File $file not found."
13
14
   exit $E_NOSUCHFILE
15 fi
16
17 read -p "Title: " title
18 cat - $file <<<$title > $file.new
20 echo "Modified file is $file.new"
```

Example 18-14. Parsing a mailbox

```
1 #!/bin/bash
2 # Script by Francisco Lobo,
3 #+ and slightly modified and commented by ABS Guide author.
4 # Used in ABS Guide with permission. (Thank you!)
 6 # This script will not run under Bash versions < 3.0.
8
9 E_MISSING_ARG=67

<u>Prev</u> **Next**

Chapter 19. I/O Redirection

There are always three default "files" open, stdin (the keyboard), stdout (the screen), and stderr (error messages output to the screen). These, and any other open files, can be redirected. Redirection simply means capturing output from a file, command, program, script, or even code block within a script (see Example 3-2) and sending it as input to another file, command, program, or script.

Each open file gets assigned a file descriptor. [1] The file descriptors for stdin, stdout, and stderr are 0, 1, and 2, respectively. For opening additional files, there remain descriptors 3 to 9. It is sometimes useful to assign one of these additional file descriptors to stdin, stdout, or stderr as a temporary duplicate link. [2] This simplifies restoration to normal after complex redirection and reshuffling (see Example 19-1).

```
1
    COMMAND_OUTPUT >
      # Redirect stdout to a file.
        # Creates the file if not present, otherwise overwrites it.
 5
       ls -lR > dir-tree.list
 6
       # Creates a file containing a listing of the directory tree.
 7
    : > filename
 8
 9
        # The > truncates file "filename" to zero length.
10
        # If file not present, creates zero-length file (same effect as 'touch').
11
        # The : serves as a dummy placeholder, producing no output.
12
13
     > filename
        # The > truncates file "filename" to zero length.
15
        # If file not present, creates zero-length file (same effect as 'touch').
        # (Same result as ": >", above, but this does not work with some shells.)
16
17
   COMMAND_OUTPUT >>
18
   # Redirect stdout to a file.
19
2.0
       # Creates the file if not present, otherwise appends to it.
2.1
2.3
      # Single-line redirection commands (affect only the line they are on):
24
25
26 1>filename
2.7
      # Redirect stdout to file "filename."
28 1>>filename
     # Redirect and append stdout to file "filename."
29
30 2>filename
31
     # Redirect stderr to file "filename."
32 2>>filename
33
     # Redirect and append stderr to file "filename."
34
     &>filename
35
    # Redirect both stdout and stderr to file "filename."
36
37
        # Note that &>>filename
38
        #+ -- attempting to redirect and *append*
39
        #+ stdout and stderr to file "filename" --
40
        #+ fails with the error message,
41
        #+ syntax error near unexpected token `>'.
42
43
     # "M" is a file descriptor, which defaults to 1, if not explicitly set.
44
      # "N" is a filename.
45
46
      # File descriptor "M" is redirect to file "N."
47 M>&N
       # "M" is a file descriptor, which defaults to 1, if not set.
```

```
49
       # "N" is another file descriptor.
50
51
52
53
        # Redirecting stdout, one line at a time.
54
        LOGFILE=script.log
55
56
        echo "This statement is sent to the log file, \"$LOGFILE\"." 1>$LOGFILE
57
        echo "This statement is appended to \"$LOGFILE\"." 1>>$LOGFILE
58
        echo "This statement is also appended to \"$LOGFILE\"." 1>>$LOGFILE
59
        echo "This statement is echoed to stdout, and will not appear in \"$LOGFILE\"."
        # These redirection commands automatically "reset" after each line.
60
61
62
63
64
        # Redirecting stderr, one line at a time.
65
        ERRORFILE=script.errors
66
67
        bad_command1 2>$ERRORFILE
                                       # Error message sent to $ERRORFILE.
68
        bad_command2 2>>$ERRORFILE
                                      # Error message appended to $ERRORFILE.
69
                                       # Error message echoed to stderr,
        bad_command3
70
                                       #+ and does not appear in $ERRORFILE.
        # These redirection commands also automatically "reset" after each line.
71
        #-----
72
1
     2>&1
2.
        # Redirects stderr to stdout.
3
        # Error messages get sent to same place as standard output.
4
5
     i>&;
        # Redirects file descriptor i to j.
6
7
        \# All output of file pointed to by i gets sent to file pointed to by j.
8
9
     >&j
10
        # Redirects, by default, file descriptor 1 (stdout) to j.
11
        # All stdout gets sent to file pointed to by j.
     0< FILENAME
      < FILENAME
 2
3
        # Accept input from a file.
4
        # Companion command to ">", and often used in combination with it.
5
 6
        # grep search-word <filename
7
8
9
     [j]<>filename
10
        # Open file "filename" for reading and writing,
11
        #+ and assign file descriptor "j" to it.
12
        # If "filename" does not exist, create it.
        # If file descriptor "j" is not specified, default to fd 0, stdin.
1.3
14
```

An application of this is writing at a specified place in a file.

Close fd 3. # ==> 1234.67890

Read only 4 characters.

Write a decimal point there.

Open "File" and assign fd 3 to it.

echo 1234567890 > File # Write string to "File".

General purpose process and command chaining tool.

15

16 17

18 19

20

21

22

23242526

27

28

exec 3<> File

read -n 4 <&3

exec 3>&-

cat File

Pine.

echo $-n \cdot > &3$

Random access, by golly.

```
# Similar to ">", but more general in effect.

# Useful for chaining commands, scripts, files, and programs together.

| cat *.txt | sort | uniq > result-file
| Sorts the output of all the .txt files and deletes duplicate lines,
| finally saves results to "result-file".
```

Multiple instances of input and output redirection and/or pipes can be combined in a single command line.

```
1 command < input-file > output-file
2
3 command1 | command2 | command3 > output-file
```

See Example 15-30 and Example A-15.

Multiple output streams may be redirected to one file.

```
1 ls -yz >> command.log 2>&1
2 # Capture result of illegal options "yz" in file "command.log."
3 # Because stderr is redirected to the file,
4 #+ any error messages will also be there.
5
6 # Note, however, that the following does *not* give the same result.
7 ls -yz 2>&1 >> command.log
8 # Outputs an error message and does not write to file.
9
10 # If redirecting both stdout and stderr,
11 #+ the order of the commands makes a difference.
```

Closing File Descriptors

Child processes inherit open file descriptors. This is why pipes work. To prevent an fd from being inherited, close it.

For a more detailed introduction to I/O redirection see Appendix E.

19.1. Using *exec*

An **exec <filename** command redirects stdin to a file. From that point on, all stdin comes from that file, rather than its normal source (usually keyboard input). This provides a method of reading a file line by line and possibly parsing each line of input using <u>sed</u> and/or <u>awk</u>.

Example 19-1. Redirecting stdin using exec

```
1 #!/bin/bash
 2 # Redirecting stdin using 'exec'.
               # Link file descriptor #6 with stdin.
 5 exec 6<&0
                     # Saves stdin.
 8 exec < data-file # stdin replaced by file "data-file"
10 read al
                    # Reads first line of file "data-file".
                    # Reads second line of file "data-file."
11 read a2
12
13 echo
14 echo "Following lines read from file."
15 echo "-----"
16 echo $a1
17 echo $a2
19 echo; echo; echo
21 exec 0<&6 6<&-
22 # Now restore stdin from fd #6, where it had been saved,
23 \#+ and close fd \#6 ( 6<\&- ) to free it for other processes to use.
25 # <&6 6<&- also works.
27 echo -n "Enter data "
28 read b1 # Now "read" functions as expected, reading from normal stdin.
29 echo "Input read from stdin."
30 echo "-----
31 \text{ echo "b1} = \$b1"
32
33 echo
35 exit 0
```

Similarly, an **exec >filename** command redirects stdout to a designated file. This sends all command output that would normally go to stdout to that file.

! exec N > filename affects the entire script or *current shell*. Redirection in the <u>PID</u> of the script or shell from that point on has changed. However . . .

N > filename affects only the newly-forked process, not the entire script or shell.

Thank you, Ahmed Darwish, for pointing this out.

Example 19-2. Redirecting stdout using exec

```
1 #!/bin/bash
2 # reassign-stdout.sh
4 LOGFILE=logfile.txt
                  # Link file descriptor #6 with stdout.
6 exec 6>&1
                    # Saves stdout.
9 exec > $LOGFILE # stdout replaced with file "logfile.txt".
10
11 # ------ #
12 # All output from commands in this block sent to file $LOGFILE.
13
14 echo -n "Logfile: "
15 date
16 echo "-----"
17 echo
18
19 echo "Output of \"ls -al\" command"
20 echo
21 ls -al
22 echo; echo
23 echo "Output of \"df\" command"
24 echo
25 df
26
29 exec 1>&6 6>&- # Restore stdout and close file descriptor #6.
30
31 echo
32 echo "== stdout now restored to default == "
33 echo
34 ls -al
35 echo
36
37 exit 0
```

Example 19-3. Redirecting both stdin and stdout in the same script with exec

```
1 #!/bin/bash
2 # upperconv.sh
3 # Converts a specified input file to uppercase.
5 E_FILE_ACCESS=70
6 E_WRONG_ARGS=71
8 if [ ! -r "$1" ]  # Is specified input file readable?
9 then
10 echo "Can't read from input file!"
11 echo "Usage: $0 input-file output-file"
12 exit $E_FILE_ACCESS
13 fi
                      # Will exit with same error
                       #+ even if input file ($1) not specified (why?).
14
15
16 if [ -z "$2" ]
17 then
18 echo "Need to specify output file."
19 echo "Usage: $0 input-file output-file"
20 exit $E_WRONG_ARGS
21 fi
22
```

```
23
24 exec 4<&0
                    # Will read from input file.
25 exec < $1
27 exec 7>&1
                     # Will write to output file.
28 exec > $2
29
                      # Assumes output file writable (add check?).
30
32 cat - | tr a-z A-Z  # Uppercase conversion.
33 # ^^^^
                         # Reads from stdin.
35 \# However, both stdin and stdout were redirected.
36 # Note that the 'cat' can be omitted.
37 # -----
39 exec 1>\&7 7>\&- # Restore stout.
40 exec 0<\&4 4<\&- # Restore stdin.
41
42 # After restoration, the following line prints to stdout as expected.
43 echo "File \"$1\" written to \"$2\" as uppercase conversion."
45 exit 0
```

I/O redirection is a clever way of avoiding the dreaded <u>inaccessible variables within a subshell</u> problem.

Example 19-4. Avoiding a subshell

```
1 #!/bin/bash
 2 # avoid-subshell.sh
 3 # Suggested by Matthew Walker.
5 Lines=0
 6
 7 echo
 9 cat myfile.txt | while read line;
10
                 do {
11
                    echo $line
12
                    (( Lines++ )); # Incremented values of this variable
                                    #+ inaccessible outside loop.

49 Line 5.
50 Line 6.
51 Line 7.
52 Line 8.
```

Notes

- [1] A file descriptor is simply a number that the operating system assigns to an open file to keep track of it. Consider it a simplified version of a file pointer. It is analogous to a *file handle* in *C*.
- Using file descriptor 5 might cause problems. When Bash creates a child process, as with exec, the child inherits fd 5 (see Chet Ramey's archived e-mail, SUBJECT: RE: File descriptor 5 is held open). Best leave this particular fd alone.

Prev **Home Next** Here Documents <u>Up</u> Redirecting Code Blocks Advanced Bash-Scripting Guide: An in-depth exploration of the art of shell scripting Chapter 19. I/O Redirection **Prev Next**

19.2. Redirecting Code Blocks

Blocks of code, such as <u>while</u>, <u>until</u>, and <u>for</u> loops, even <u>if/then</u> test blocks can also incorporate redirection of stdin. Even a function may use this form of redirection (see <u>Example 23-11</u>). The < operator at the end of the code block accomplishes this.

Example 19-5. Redirected while loop

```
1 #!/bin/bash
 2 # redir2.sh
 4 if [ -z "$1" ]
 5 then
                            # Default, if no filename specified.
 6 Filename=names.data
 7 else
8 Filename=$1
9 fi
10 #+ Filename=${1:-names.data}
11 # can replace the above test (parameter substitution).
13 count=0
14
15 echo
17 while [ "$name" != Smith | # Why is variable $name in quotes?
19
    read name
                              # Reads from $Filename, rather than stdin.
   echo $name
20
21 let "count += 1"
                             # Redirects stdin to file $Filename.
22 done <"$Filename"
        ^^^^^
23 #
25 echo; echo "$count names read"; echo
27 exit 0
28
29 # Note that in some older shell scripting languages,
30 #+ the redirected loop would run as a subshell.
31 # Therefore, $count would return 0, the initialized value outside the loop.
32 # Bash and ksh avoid starting a subshell *whenever possible*,
33 #+ so that this script, for example, runs correctly.
34 # (Thanks to Heiner Steven for pointing this out.)
36 # However . . .
37 # Bash *can* sometimes start a subshell in a PIPED "while-read" loop,
38 #+ as distinct from a REDIRECTED "while" loop.
40 abc=hi
41 echo -e "1\n2\n3" | while read 1
42 do abc="$1"
43
       echo $abc
44 done
45 echo $abc
46
47 # Thanks, Bruno de Oliveira Schneider, for demonstrating this
48 #+ with the above snippet of code.
49 # And, thanks, Brian Onn, for correcting an annotation error.
```

Example 19-6. Alternate form of redirected while loop

```
1 #!/bin/bash
 3 # This is an alternate form of the preceding script.
 5 # Suggested by Heiner Steven
 6 #+ as a workaround in those situations when a redirect loop
 7 #+ runs as a subshell, and therefore variables inside the loop
 8 # +do not keep their values upon loop termination.
10
11 if [ -z "$1" ]
12 then
13 Filename=names.data # Default, if no filename specified.
14 else
15 Filename=$1
16 fi
17
18
19 exec 3<&0
                            # Save stdin to file descriptor 3.
20 exec 0<"$Filename" # Redirect standard input.
2.1
22 count=0
23 echo
24
25
26 while [ "$name" != Smith ]
28 read name
                           # Reads from redirected stdin ($Filename).
29 echo $name
30 let "count += 1"
31 done
                            # Loop reads from file $Filename
32
                            #+ because of line 20.
33
34 # The original version of this script terminated the "while" loop with
35 #+ done <"$Filename"
36 # Exercise:
37 # Why is this unnecessary?
38
40 exec 0<&3
                            # Restore old stdin.
41 exec 3<&-
                            # Close temporary fd 3.
42
43 echo; echo "$count names read"; echo
44
45 exit 0
```

Example 19-7. Redirected until loop

```
1 #!/bin/bash
2 # Same as previous example, but with "until" loop.
3
4 if [ -z "$1" ]
5 then
6 Filename=names.data # Default, if no filename specified.
7 else
8 Filename=$1
9 fi
10
11 # while [ "$name" != Smith ]
12 until [ "$name" = Smith ] # Change != to =.
```

```
13 do
14 read name # Reads from $Filename, rather than stdin.
15 echo $name
16 done <"$Filename" # Redirects stdin to file $Filename.
17 # ^^^^^^^^^^^
18
19 # Same results as with "while" loop in previous example.
20
21 exit 0
```

Example 19-8. Redirected for loop

```
1 #!/bin/bash
3 if [ -z "$1" ]
4 then
5 Filename=names.data # Default, if no filename specified.
 6 else
7 Filename=$1
 8 fi
 9
10 line_count=`wc $Filename | awk '{ print $1 }'`
11 # Number of lines in target file.
13 # Very contrived and kludgy, nevertheless shows that
14 #+ it's possible to redirect stdin within a "for" loop...
15 #+ if you're clever enough.
16 #
17 # More concise is line_count=$(wc -1 < "$Filename")
18
19
20 for name in `seq $line_count` # Recall that "seq" prints sequence of numbers.
21 # while [ "$name" != Smith ] -- more complicated than a "while" loop --
22 do
23 read name
                               # Reads from $Filename, rather than stdin.
24 echo $name
25 if [ "$name" = Smith ]
                              # Need all this extra baggage here.
26 then
27
     break
28 fi
29 done <"$Filename"
                              # Redirects stdin to file $Filename.
30 # ^^^^^^
31
32 exit 0
```

We can modify the previous example to also redirect the output of the loop.

Example 19-9. Redirected for loop (both stdin and stdout redirected)

```
1 #!/bin/bash
2
3 if [ -z "$1" ]
4 then
5 Filename=names.data  # Default, if no filename specified.
6 else
7 Filename=$1
8 fi
9
10 Savefile=$Filename.new  # Filename to save results in.
```

```
11 FinalName=Jonah
                                   # Name to terminate "read" on.
12
13 line_count=`wc $Filename | awk '{ print $1 }'` # Number of lines in target file.
14
15
16 for name in `seq $line_count`
17 do
18 read name
19 echo "$name"
20 if [ "$name" = "$FinalName" ]
21 then
22
     break
23 fi
24 done < "$Filename" > "$Savefile" # Redirects stdin to file $Filename,
25 # ^^^^^^^^^^^^^^^^^^^^^
25 #
                                         and saves it to backup file.
27 exit 0
```

Example 19-10. Redirected if/then test

```
1 #!/bin/bash
 3 if [ -z "$1" ]
4 then
5 Filename=names.data # Default, if no filename specified.
6 else
7 Filename=$1
8 fi
9
10 TRUE=1
11
12 if [ "$TRUE" ]
                        # if true and if: also work.
13 then
14 read name
15 echo $name
16 fi <"$Filename"
17 # ^^^^^^^
18
19 # Reads only first line of file.
20 \# An "if/then" test has no way of iterating unless embedded in a loop.
2.1
22 exit 0
```

Example 19-11. Data file names.data for above examples

```
1 Aristotle
2 Belisarius
3 Capablanca
4 Euler
5 Goethe
6 Hamurabi
7 Jonah
8 Laplace
9 Maroczy
10 Purcell
11 Schmidt
12 Semmelweiss
13 Smith
14 Turing
```

```
15 Venn
16 Wilson
17 Znosko-Borowski
18
19 # This is a data file for
20 #+ "redir2.sh", "redir3.sh", "redir4.sh", "redir4a.sh", "redir5.sh".
```

Redirecting the stdout of a code block has the effect of saving its output to a file. See Example 3-2.

<u>Here documents</u> are a special case of redirected code blocks. That being the case, it should be possible to feed the output of a *here document* into the stdin for a *while loop*.

```
1 # This example by Albert Siersema
 2 # Used with permission (thanks!).
 3
 4 function doesOutput()
 5 # Could be an external command too, of course.
 6 # Here we show you can use a function as well.
 7 {
   ls -al *.jpg | awk '{print $5,$9}'
 9 }
10
11
12 nr=0
                # We want the while loop to be able to manipulate these and
               #+ to be able to see the changes after the while finished.
13 totalSize=0
15 while read fileSize fileName; do
16 echo "$fileName is $fileSize bytes"
17
     let nr++
   totalSize=$((totalSize+fileSize)) # Or: "let totalSize+=fileSize"
18
19 done << EOF
20 $ (doesOutput)
21 EOF
23 echo "$nr files totaling $totalSize bytes"
```

Prev Chapter 19. I/O Redirection

19.3. Applications

Clever use of I/O redirection permits parsing and stitching together snippets of command output (see <u>Example 14-7</u>). This permits generating report and log files.

Example 19-12. Logging events

```
1 #!/bin/bash
 2 # logevents.sh
 3 # Author: Stephane Chazelas.
 4 # Used in ABS Guide with permission.
 6 # Event logging to a file.
 7 # Must be run as root (for write access in /var/log).
 9 ROOT_UID=0 # Only users with $UID 0 have root privileges.
10 E_NOTROOT=67 # Non-root exit error.
11
12
13 if [ "$UID" -ne "$ROOT_UID" ]
14 then
15 echo "Must be root to run this script."
16 exit $E_NOTROOT
17 fi
18
20 FD_DEBUG1=3
21 FD_DEBUG2=4
22 FD_DEBUG3=5
24 # === Uncomment one of the two lines below to activate script. ===
25 # LOG_EVENTS=1
26 # LOG_VARS=1
27
29 log() # Writes time and date to log file.
31 echo "\$(date) \$*" > \& 7 # This *appends* the date to the file.
32 # ^^^^^ command substitution
33
                              # See below.
34 }
35
36
37
38 case $LOG_LEVEL in
39 1) exec 3>&2 4> /dev/null 5> /dev/null;;
40 2) exec 3>&2 4>&2 5> /dev/null;;
41 3) exec 3>&2 4>&2 5>&2;;
42 *) exec 3> /dev/null 4> /dev/null 5> /dev/null;;
43 esac

 Redirecting Code Blocks
 Up
 Subshells

 Advanced Bash-Scripting Guide: An in-depth exploration of the art of shell scripting

 Prev
 Next

Chapter 20. Subshells

Running a shell script launches a new process, a *subshell*.

```
Definition: A subshell is a process launched by a shell (or shell script).
```

A subshell is a separate instance of the command processor -- the *shell* that gives you the prompt at the console or in an *xterm* window. Just as your commands are interpreted at the command line prompt, similarly does a script <u>batch-process</u> a list of commands. Each shell script running is, in effect, a subprocess (<u>child process</u>) of the <u>parent</u> shell.

A shell script can itself launch subprocesses. These *subshells* let the script do parallel processing, in effect executing multiple subtasks simultaneously.

```
1 #!/bin/bash
 2 # subshell-test.sh
 5 # Inside parentheses, and therefore a subshell . . .
 6 while [ 1 ] # Endless loop.
8 echo "Subshell running . . . "
9 done
10)
12 # Script will run forever,
13 #+ or at least until terminated by a Ctl-C.
15 exit $? # End of script (but will never get here).
16
17
18
19 Now, run the script:
20 sh subshell-test.sh
22 And, while the script is running, from a different xterm:
23 ps -ef | grep subshell-test.sh
          PID PPID C STIME TTY TIME CMD
2698 2502 0 14:26 pts/4 00:00:00 sh subshell-test.sh
25 UID
26 500
           2699 2698 21 14:26 pts/4 00:00:24 sh subshell-test.sh
27 500
2.8
            ^^^^
29
30
31 Analysis:
32 PID 2698, the script, launched PID 2699, the subshell.
34 Note: The "UID ..." line would be filtered out by the "grep" command,
35 but is shown here for illustrative purposes.
```

In general, an <u>external command</u> in a script <u>forks off</u> a subprocess, [1] whereas a Bash <u>builtin</u> does not. For this reason, builtins execute more quickly than their external command equivalents.

Command List within Parentheses

```
(command1; command2; command3; ...)
```

A command list embedded between parentheses runs as a subshell.

Variables in a subshell are *not* visible outside the block of code in the subshell. They are not accessible to the parent process, to the shell that launched the subshell. These are, in effect, <u>local variables</u>.

Example 20-1. Variable scope in a subshell

```
1 #!/bin/bash
2 # subshell.sh
4 echo
 6 echo "We are outside the subshell."
7 echo "Subshell level OUTSIDE subshell = $BASH_SUBSHELL"
8 # Bash, version 3, adds the new $BASH_SUBSHELL variable.
9 echo; echo
10
11 outer_variable=Outer
12 global_variable=
13 # Define global variable for "storage" of
14 #+ value of subshell variable.
15
16 (
17 echo "We are inside the subshell."
18 echo "Subshell level INSIDE subshell = $BASH_SUBSHELL"
19 inner_variable=Inner
21 echo "From inside subshell, \"inner_variable\" = $inner_variable"
22 echo "From inside subshell, \"outer\" = $outer_variable"
23
24 global_variable="$inner_variable"  # Will this allow "exporting"
2.5
                                    #+ a subshell variable?
26)
27
28 echo; echo
29 echo "We are outside the subshell."
30 echo "Subshell level OUTSIDE subshell = $BASH_SUBSHELL"
31 echo
32
33 if [ -z "$inner_variable" ]
34 then
35 echo "inner_variable undefined in main body of shell"
36 else
37 echo "inner_variable defined in main body of shell"
38 fi
39
40 echo "From main body of shell, \"inner_variable\" = $inner_variable"
41 # $inner_variable will show as blank (uninitialized)
42 #+ because variables defined in a subshell are "local variables".
43 # Is there a remedy for this?
44 echo "global_variable = "$global_variable"  # Why doesn't this work?
4.5
46 echo
47
48 # -----
49
50 # Additionally ...
52 echo "----"; echo
54 var=41
                                                       # Global variable.
55
56 (let "var+=1"; echo "\$var INSIDE subshell = $var") # 42
58 echo "\$var OUTSIDE subshell = $var"
59 # Variable operations inside a subshell, even to a GLOBAL variable
```

```
60 #+ do not affect the value of the variable outside the subshell!
61
62
63 exit 0
64
65 # Question:
66 # -----
67 # Once having exited a subshell,
68 #+ is there any way to reenter that very same subshell
69 #+ to modify or access the subshell variables?
```

See also Example 31-2.

Definition: The *scope* of a variable is the context in which it has meaning, in which it has a *value* that can be referenced. For example, the scope of a <u>local variable</u> lies only within the function, block of code, or subshell within which it is defined.

While the <u>\$BASH_SUBSHELL</u> internal variable indicates the nesting level of a subshell, the <u>\$SHLVL</u> variable *shows no change* within a subshell.

Directory changes made in a subshell do not carry over to the parent shell.

Example 20-2. List User Profiles

```
1 #!/bin/bash
2 # allprofs.sh: print all user profiles
3
4 # This script written by Heiner Steven, and modified by the document author.
5
6 FILE=.bashrc # File containing user profile,
7 #+ was ".profile" in original script.
8
9 for home in `awk -F: '{print $6}' /etc/passwd`
10 do
11 [ -d "$home" ] || continue # If no home directory, go to next.
12 [ -r "$home" ] || continue # If not readable, go to next.
13 (cd $home; [ -e $FILE ] && less $FILE)
14 done
15
16 # When script terminates, there is no need to 'cd' back to original directory,
17 #+ because 'cd $home' takes place in a subshell.
18
19 exit 0
```

A subshell may be used to set up a "dedicated environment" for a command group.

```
2 COMMAND2
3 COMMAND3
4 (
5   IFS=:
6   PATH=/bin
7   unset TERMINFO
8   set -C
9   shift 5
10   COMMAND4
11   COMMAND5
12   exit 3 # Only exits the subshell!
13 )
14 # The parent shell has not been affected, and the environment is preserved.
15 COMMAND6
16 COMMAND7
```

As seen here, the <u>exit</u> command only terminates the subshell in which it is running, *not* the parent shell or script.

One application of such a "dedicated environment" is testing whether a variable is defined.

Another application is checking for a lock file:

```
1 if (set -C; : > lock_file) 2> /dev/null
2 then
3 : # lock_file didn't exist: no user running the script
4 else
5 echo "Another user is already running that script."
6 exit 65
7 fi
8
9 # Code snippet by Stéphane Chazelas,
10 #+ with modifications by Paulo Marcel Coelho Aragao.
```

Processes may execute in parallel within different subshells. This permits breaking a complex task into subcomponents processed concurrently.

Example 20-3. Running parallel processes in subshells

```
1  (cat list1 list2 list3 | sort | uniq > list123) &
2   (cat list4 list5 list6 | sort | uniq > list456) &
3   # Merges and sorts both sets of lists simultaneously.
4   # Running in background ensures parallel execution.
5   #
6   # Same effect as
7   # cat list1 list2 list3 | sort | uniq > list123 &
8   # cat list4 list5 list6 | sort | uniq > list456 &
9
10   wait  # Don't execute the next command until subshells finish.
11
```

Redirecting I/O to a subshell uses the "I" pipe operator, as in ls -al | (command).

A command block between curly braces does not launch a subshell.

{ command1; command2; command3; . . . commandN; }

Notes

[1] An external command invoked with an exec does not (usually) fork off a subprocess / subshell.

Chapter 21. Restricted Shells

Disabled commands in restricted shells

Running a script or portion of a script in *restricted* mode disables certain commands that would otherwise be available. This is a security measure intended to limit the privileges of the script user and to minimize possible damage from running the script.

Using cd to change the working directory.

Changing the values of the \$PATH, \$SHELL, \$BASH_ENV, or \$ENV environmental variables.

Reading or changing the \$SHELLOPTS, shell environmental options.

Output redirection.

Invoking commands containing one or more /'s.

Invoking <u>exec</u> to substitute a different process for the shell.

Various other commands that would enable monkeying with or attempting to subvert the script for an unintended purpose.

Getting out of restricted mode within the script.

Example 21-1. Running a script in restricted mode

```
1 #!/bin/bash
 3 # Starting the script with "#!/bin/bash -r"
 4 #+ runs entire script in restricted mode.
 6 echo
 8 echo "Changing directory."
9 cd /usr/local
10 echo "Now in `pwd`"
11 echo "Coming back home."
12 cd
13 echo "Now in `pwd`"
14 echo
15
16 # Everything up to here in normal, unrestricted mode.
18 set -r
19 # set --restricted has same effect.
20 echo "==> Now in restricted mode. <=="
22 echo
23 echo
25 echo "Attempting directory change in restricted mode."
27 echo "Still in `pwd`"
29 echo
30 echo
32 echo "\$SHELL = $SHELL"
33 echo "Attempting to change shell in restricted mode."
34 SHELL="/bin/ash"
35 echo
36 echo "\$SHELL= $SHELL"
38 echo
39 echo
40
```

```
41 echo "Attempting to redirect output in restricted mode."
42 ls -1 /usr/bin > bin.files
43 ls -1 bin.files # Try to list attempted file creation effort.
44
45 echo
46
47 exit 0
```

Chapter 22. Process Substitution

Piping the stdout of a command into the stdin of another is a powerful technique. But, what if you need to pipe the stdout of multiple commands? This is where process substitution comes in.

Process substitution feeds the output of a process (or processes) into the stdin of another process.

Template

Command list enclosed within parentheses

```
>(command_list)
```

```
<(command_list)
```

Process substitution uses /dev/fd/<n> files to send the results of the process(es) within parentheses to another process. [1]

1 There is *no* space between the the "<" or ">" and the parentheses. Space there would give an error message.

```
bash$ echo > (true)
 /dev/fd/63
 bash$ echo <(true)
 /dev/fd/63
```

Bash creates a pipe with two file descriptors, --fIn and fOut--. The stdin of true connects to fOut (dup2(fOut, 0)), then Bash passes a /dev/fd/fIn argument to echo. On systems lacking /dev/fd/<n> files, Bash may use temporary files. (Thanks, S.C.)

Process substitution can compare the output of two different commands, or even the output of different options to the same command.

```
bash$ comm <(ls -1) <(ls -al)
total 12
             1 bozo bozo 78 Mar 10 12:58 File0
-rw-rw-r--
-rw-rw-r-- 1 bozo bozo
-rw-rw-r-- 1 bozo bozo
                                42 Mar 10 12:58 File2
                              103 Mar 10 12:58 t2.sh
       total 20
       drwxrwxrwx 2 bozo bozo 4096 Mar 10 18:10 .
       drwx---- 72 bozo bozo
                                     4096 Mar 10 17:58 ..
        -rw-rw-r-- 1 bozo bozo 78 Mar 10 12:58 File0 -rw-rw-r-- 1 bozo bozo 42 Mar 10 12:58 File2
        -rw-rw-r-- 1 bozo bozo 103 Mar 10 12:58 t2.sh
```

Using process substitution to compare the contents of two directories (to see which filenames are in one, but not the other):

```
1 diff <(ls $first_directory) <(ls $second_directory)</pre>
```

Some other usages and uses of process substitution:

```
1 read -a list < <( od -Ad -w24 -t u2 /dev/urandom )</pre>
2 # Read a list of random numbers from /dev/urandom,
3 #+ process with "od"
4 #+ and feed into stdin of "read" . . .
```

```
5
6 # From "insertion-sort.bash" example script.
7 # Courtesy of JuanJo Ciarlante.
```

```
1 cat <(ls -1)
2 # Same as
               ls -l | cat
4 sort -k 9 <(ls -l /bin) <(ls -l /usr/bin) <(ls -l /usr/X11R6/bin)
5 # Lists all the files in the 3 main 'bin' directories, and sorts by filename.
6 # Note that three (count 'em) distinct commands are fed to 'sort'.
8
9 diff <(command1) <(command2)
                                 # Gives difference in command output.
10
11 tar cf > (bzip2 -c > file.tar.bz2) $directory_name
12 # Calls "tar cf /dev/fd/?? $directory_name", and "bzip2 -c > file.tar.bz2".
13 #
14 # Because of the /dev/fd/<n> system feature,
15 # the pipe between both commands does not need to be named.
16 #
17 # This can be emulated.
18 #
19 bzip2 -c < pipe > file.tar.bz2&
20 tar cf pipe $directory_name
21 rm pipe
22 # or
23 exec 3>&1
24 tar cf /dev/fd/4 $directory_name 4>&1 >&3 3>&- | bzip2 -c > file.tar.bz2 3>&-
25 exec 3>&-
26
27
28 # Thanks, Stéphane Chazelas
```

A reader sent in the following interesting example of process substitution.

```
1 # Script fragment taken from SuSE distribution:
                                 _____#
4 while read des what mask iface; do
5 # Some commands ...
6 done < <(route -n)
7 # ^ First < is redirection, second is process substitution.
9 # To test it, let's make it do something.
10 while read des what mask iface; do
11 echo $des $what $mask $iface
12 done < <(route -n)
13
14 # Output:
15 # Kernel IP routing table
16 # Destination Gateway Genmask Flags Metric Ref Use Iface
17 # 127.0.0.0 0.0.0.0 255.0.0.0 U 0 0 1 o
18 # -
19
20 # As Stéphane Chazelas points out,
21 #+ an easier-to-understand equivalent is:
22 route -n |
23 while read des what mask iface; do # Variables set from output of pipe.
24
    echo $des $what $mask $iface
25 done # This yields the same output as above.
        # However, as Ulrich Gayer points out . . .
26
27
         #+ this simplified equivalent uses a subshell for the while loop,
28
         #+ and therefore the variables disappear when the pipe terminates.
29
30 # -----#
31
```

```
32 \ \text{\#} However, Filip Moritz comments that there is a subtle difference
33 \#+ between the above two examples, as the following shows.
34
35 (
36 route -n | while read x; do ((y++)); done
37 echo $y # $y is still unset
39 while read x; do ((y++)); done < <(route -n)
40 echo y # y has the number of lines of output of route -n
41)
42
43 More generally spoken
44 (
45 : | x=x
46 # seems to start a subshell like
47 : | (x=x)
48 # while
49 x=x < <(:)
50 # does not
51)
52
53 # This is useful, when parsing csv and the like.
54 # That is, in effect, what the original SuSE code fragment does.
```

Notes

[1] This has the same effect as a <u>named pipe</u> (temp file), and, in fact, named pipes were at one time used in process substitution.

Restricted Shells Up Functions

Advanced Bash-Scripting Guide: An in-depth exploration of the art of shell scripting

Prev Next

<u>Prev</u> <u>Next</u>

Chapter 23. Functions

Like "real" programming languages, Bash has functions, though in a somewhat limited implementation. A function is a subroutine, a code block that implements a set of operations, a "black box" that performs a specified task. Wherever there is repetitive code, when a task repeats with only slight variations in procedure, then consider using a function.

```
function function_name {
command...
}
or
function_name() {
command...
```

This second form will cheer the hearts of C programmers (and is more portable).

As in C, the function's opening bracket may optionally appear on the second line.

```
function_name()
command...
}
```

A function may be "compacted" into a single line.

```
1 fun () { echo "This is a function"; echo; }
```

In this case, however, a *semicolon* must follow the final command in the function.

```
1 fun () { echo "This is a function"; echo } # Error!
```

Functions are called, *triggered*, simply by invoking their names.

Example 23-1. Simple functions

```
1 #!/bin/bash
3 JUST_A_SECOND=1
 5 funky ()
 6 { # This is about as simple as functions get.
   echo "This is a funky function."
 8 echo "Now exiting funky function."
 9 } # Function declaration must precede call.
10
11
12 fun ()
13 { # A somewhat more complex function.
    REPEATS=30
15
16
17
    echo
18 echo "And now the fun really begins."
```

```
19
  echo
20
21 sleep $JUST_A_SECOND
                  # Hey, wait a second!
22 while [ $i -lt $REPEATS ]
23 do
24
   25
   echo "<-----"
26
   echo "<---->"
27
   echo
   let "i+=1"
28
29 done
30 }
31
  # Now, call the functions.
32
33
34 funky
35 fun
36
37 exit 0
```

The function definition must precede the first call to it. There is no method of "declaring" the function, as, for example, in C.

```
2 # Will give an error message, since function "f1" not yet defined.
4 declare -f f1
                   # This doesn't help either.
5 f1
                     # Still an error message.
7 # However...
9
10 f1 ()
11 {
12 echo "Calling function \"f2\" from within function \"f1\"."
13 f2
14 }
15
16 f2 ()
17 {
18 echo "Function \"f2\"."
19 }
21 fl # Function "f2" is not actually called until this point,
     #+ although it is referenced before its definition.
23
     # This is permissible.
24
25 # Thanks, S.C.
```

It is even possible to nest a function within another function, although this is not very useful.

```
1 f1 ()
2 {
3
4   f2 () # nested
5   {
6    echo "Function \"f2\", inside \"f1\"."
7   }
8
9 }
10
11 f2 # Gives an error message.
12 # Even a preceding "declare -f f2" wouldn't help.
13
```

```
14 echo
15
16 f1 # Does nothing, since calling "f1" does not automatically call "f2".
17 f2 # Now, it's all right to call "f2",
18 #+ since its definition has been made visible by calling "f1".
19
20 # Thanks, S.C.
```

Function declarations can appear in unlikely places, even where a command would otherwise go.

```
1 ls -l | foo() { echo "foo"; } # Permissible, but useless.
 3
 4
5 if [ "$USER" = bozo ]
6 then
7 bozo_greet () # Function definition embedded in an if/then construct.
     echo "Hello, Bozo."
10 }
11 fi
12
13 bozo_greet  # Works only for Bozo, and other users get an error.
14
15
16
17 # Something like this might be useful in some contexts.
18 NO_EXIT=1 # Will enable function definition below.
19
20 [[ $NO_EXIT -eq 1 ]] && exit() { true; } # Function definition in an "and-list".
21 # If $NO_EXIT is 1, declares "exit ()".
22 # This disables the "exit" builtin by aliasing it to "true".
2.3
24 exit # Invokes "exit ()" function, not "exit" builtin.
2.5
2.6
27
28 # Or, similarly:
29 filename=file1
31 [ -f "$filename" ] &&
32 foo () { rm -f "$filename"; echo "File "$filename" deleted."; } ||
33 foo () { echo "File "$filename" not found."; touch bar; }
34
35 foo
36
37 # Thanks, S.C. and Christopher Head
```

What happens when different versions of the same function appear in a script?

```
1 # As Yan Chen points out,
2 # when a function is defined multiple times,
3 # the final version is what is invoked.
4 # This is not, however, particularly useful.
5
6 func ()
7 {
8 echo "First version of func ()."
9 }
10
11 func ()
12 {
13 echo "Second version of func ()."
14 }
15
16 func # Second version of func ().
```

```
17
18 exit $?
19
20 # It is even possible to use functions to override
21 #+ or preempt system commands.
22 # Of course, this is *not* advisable.
```

23.1. Complex Functions and Function Complexities

Functions may process arguments passed to them and return an exit status to the script for further processing.

```
1 function_name $arg1 $arg2
```

The function refers to the passed arguments by position (as if they were <u>positional parameters</u>), that is, \$1, \$2, and so forth.

Example 23-2. Function Taking Parameters

```
1 #!/bin/bash
2 # Functions and parameters
4 DEFAULT=default
                                            # Default param value.
 6 func2 () {
   if [ -z "$1" ]
                                            # Is parameter #1 zero length?
 8 then
9
      echo "-Parameter #1 is zero length.-" # Or no parameter passed.
10 else
11
      echo "-Param #1 is \"$1\".-"
    fi
12
13
14
    variable=${1-$DEFAULT}
    echo "variable = $variable"
15
                                            #+ parameter substitution show?
16
17
                                            # It distinguishes between
18
                                            #+ no param and a null param.
19
20 if [ "$2" ]
21 then
22 echo "-Parameter #2 is \"$2\".-"
23 fi
24
25 return 0
26 }
27
28 echo
29
30 echo "Nothing passed."
31 func2
                                # Called with no params
32 echo
33
35 echo "Zero-length parameter passed."
                # Called with zero-length param
36 func2 ""
37 echo
39 echo "Null parameter passed."
40 func2 "$uninitialized_param"  # Called with uninitialized param
41 echo
42
43 echo "One parameter passed."
44 func2 first # Called with one param
45 echo
46
47 echo "Two parameters passed."
48 func2 first second # Called with two params
```

```
49 echo
50
51 echo "\"\" \"second\" passed."
52 func2 "" second # Called with zero-length first parameter
                        # and ASCII string as a second one.
55 exit 0
```

1 The shift command works on arguments passed to functions (see Example 33-15).

But, what about command-line arguments passed to the script? Does a function see them? Well, let's clear up the confusion.

Example 23-3. Functions and command-line args passed to the script

```
1 #!/bin/bash
2 # func-cmdlinearg.sh
3 # Call this script with a command-line argument,
4 #+ something like $0 arg1.
6
7 func ()
8
9 {
10 echo "$1"
11 }
12
13 echo "First call to function: no arg passed."
14 echo "See if command-line arg is seen."
15 func
16 # No! Command-line arg not seen.
18 echo "-----"
20 echo "Second call to function: command-line arg passed explicitly."
21 func $1
22 # Now it's seen!
23
24 exit 0
```

In contrast to certain other programming languages, shell scripts normally pass only value parameters to functions. Variable names (which are actually pointers), if passed as parameters to functions, will be treated as string literals. Functions interpret their arguments literally.

<u>Indirect variable references</u> (see Example 34-2) provide a clumsy sort of mechanism for passing variable pointers to functions.

Example 23-4. Passing an indirect reference to a function

```
1 #!/bin/bash
2 # ind-func.sh: Passing an indirect reference to a function.
4 echo_var ()
5 {
6 echo "$1"
7 }
```

```
9 message=Hello
10 Hello=Goodbye
11
12 echo_var "$message"
                           # Hello
13 # Now, let's pass an indirect reference to the function.
14 echo_var "${!message}" # Goodbye
15
16 echo "----"
17
18 # What happens if we change the contents of "hello" variable?
19 Hello="Hello, again!"
20 echo_var "$message"
                           # Hello
21 echo_var "${!message}" # Hello, again!
23 exit 0
```

The next logical question is whether parameters can be dereferenced after being passed to a function.

Example 23-5. Dereferencing a parameter passed to a function

```
1 #!/bin/bash
 2 # dereference.sh
 3 # Dereferencing parameter passed to a function.
 4 # Script by Bruce W. Clare.
 6 dereference ()
 7 {
 8
       y=\"$1" # Name of variable.
 9
        echo $y
                # $Junk
10
       x=`eval "expr \"$y\" "`
11
12
       echo $1=$x
        eval "$1=\"Some Different Text \"" # Assign new value.
13
14 }
15
16 Junk="Some Text"
17 echo $Junk "before"
                        # Some Text before
18
19 dereference Junk
20 echo $Junk "after"  # Some Different Text after
21
22 exit 0
```

Example 23-6. Again, dereferencing a parameter passed to a function

```
1 4
15 echo -n "Enter a value "
16 eval 'echo -n "[$'$1'] "' # Previous value.
17 # eval echo -n "[\$$1] " # Easier to understand,
                               #+ but loses trailing space in user prompt.
19 read local_var
20 [ -n "$local_var" ] && eval $1=\$local_var
21
22
   # "And-list": if "local_var" then set "$1" to its value.
23 }
2.4
25 echo
2.6
27 while [ "$icount" -le "$ITERATIONS" ]
28 do
29 my_read var
   echo "Entry #$icount = $var"
   let "icount += 1"
31
32
   echo
33 done
34
35
36 # Thanks to Stephane Chazelas for providing this instructive example.
37
38 exit 0
```

Exit and Return

exit status

Functions return a value, called an *exit status*. The exit status may be explicitly specified by a **return** statement, otherwise it is the exit status of the last command in the function (0 if successful, and a non-zero error code if not). This <u>exit status</u> may be used in the script by referencing it as <u>\$?</u>. This mechanism effectively permits script functions to have a "return value" similar to C functions.

return

Terminates a function. A **return** command [1] optionally takes an *integer* argument, which is returned to the calling script as the "exit status" of the function, and this exit status is assigned to the variable \$?.

Example 23-7. Maximum of two numbers

```
1 #!/bin/bash
 2 # max.sh: Maximum of two integers.
4 E_PARAM_ERR=250  # If less than 2 params passed to function.
5 EQUAL=251 # Return value if both params equal.
 6 # Error values out of range of any
7 #+ params that might be fed to the function.
 9 max2 ()
                      # Returns larger of two numbers.
10 {
                      # Note: numbers compared must be less than 257.
11 if [ -z "$2" ]
12 then
13 return $E_PARAM_ERR
14 fi
1.5
16 if [ "$1" -eq "$2" ]
17 then
18 return $EQUAL
19 else
20 if [ "$1" -gt "$2" ]
```

```
then
21
22 return $1
23 else
24 return $2
25 fi
26 fi
27 }
28
29 max2 33 34
30 return_val=$?
31
32 if [ "$return_val" -eq $E_PARAM_ERR ]
33 then
34 echo "Need to pass two parameters to the function."
35 elif [ "$return_val" -eq $EQUAL ]
   then
37
   echo "The two numbers are equal."
38 else
39 echo "The larger of the two numbers is $return_val."
40 fi
41
42
43 exit 0
44
45 # Exercise (easy):
47 # Convert this to an interactive script,
48 #+ that is, have the script ask for input (two numbers).
```

For a function to return a string or array, use a dedicated variable.

```
1 count_lines_in_etc_passwd()
2 {
3 [[ -r /etc/passwd ]] && REPLY=$(echo $(wc -l < /etc/passwd))
4 # If /etc/passwd is readable, set REPLY to line count.
5 # Returns both a parameter value and status information.
    # The 'echo' seems unnecessary, but . . .
    #+ it removes excess whitespace from the output.
8 }
9
10 if count_lines_in_etc_passwd
11 then
12 echo "There are $REPLY lines in /etc/passwd."
13 else
14 echo "Cannot count lines in /etc/passwd."
15 fi
16
17 # Thanks, S.C.
```

Example 23-8. Converting numbers to Roman numerals

```
1 #!/bin/bash
2
3 # Arabic number to Roman numeral conversion
4 # Range: 0 - 200
5 # It's crude, but it works.
6
7 # Extending the range and otherwise improving the script is left as an exercise.
8
9 # Usage: roman number-to-convert
10
11 LIMIT=200
```

```
12 E_ARG_ERR=65
13 E_OUT_OF_RANGE=66
14
15 if [ -z "$1" ]
   echo "Usage: `basename $0` number-to-convert"
18 exit $E_ARG_ERR
19 fi
20
21 num=$1
22 if [ "$num" -gt $LIMIT ]

```

See also Example 10-28.

! The largest positive integer a function can return is 255. The **return** command is closely tied to the concept of <u>exit status</u>, which accounts for this particular limitation. Fortunately, there are various <u>workarounds</u> for those situations requiring a large integer return value from a function.

Example 23-9. Testing large return values in a function

```
1 #!/bin/bash
 2 # return-test.sh
4 # The largest positive value a function can return is 255.
6 return_test () # Returns whatever passed to it.
7 {
8 return $1
9 }
10
                   # o.k.
11 return_test 27
12 echo $?
                     # Returns 27.
14 return_test 255
                     # Still o.k.
15 echo $?
                      # Returns 255.
16
17 return_test 257  # Error!
18 echo $?
                     # Returns 1 (return code for miscellaneous error).
19
20 # -----
21 return_test -151896  # Do large negative numbers work?
22 echo $?  # Will this return -151896?
                     # No! It returns 168.
24 # Version of Bash before 2.05b permitted
25 #+ large negative integer return values.
26 # Newer versions of Bash plug this loophole.
27 # This may break older scripts.
28 # Caution!
30
31 exit 0
```

A workaround for obtaining large integer "return values" is to simply assign the "return value" to a global variable.

```
1 Return_Val= # Global variable to hold oversize return value of function.
3 alt_return_test ()
4 {
5 fvar=$1
6 Return_Val=$fvar
7 return # Returns 0 (success).
8 }
9
10 alt_return_test 1
                                     # 0
11 echo $?
12 echo "return value = $Return_Val"
                                      # 1
14 alt_return_test 256
15 echo "return value = $Return_Val" # 256
17 alt_return_test 257
18 echo "return value = $Return_Val" # 257
19
20 alt_return_test 25701
21 echo "return value = $Return_Val"
                                    #25701
```

A more elegant method is to have the function **echo** its "return value to stdout," and then capture it by <u>command substitution</u>. See the <u>discussion of this</u> in <u>Section 33.8</u>.

Example 23-10. Comparing two large integers

```
1 #!/bin/bash
 2 # max2.sh: Maximum of two LARGE integers.
 4 # This is the previous "max.sh" example,
 5 #+ modified to permit comparing large integers.
 6
7 EOUAL=0
                    # Return value if both params equal.
8 E_PARAM_ERR=-99999 # Not enough params passed to function.
       ^^^^^ Out of range of any params that might be passed.
10
11 max2 ()
                   # "Returns" larger of two numbers.
12 {
13 if [ -z "$2" ]
14 then
15 echo $E_PARAM_ERR
16 return
17 fi
18
19 if [ "$1" -eq "$2" ]
20 then
21 echo $EQUAL
22
    return
23 else
24
   if [ "$1" -qt "$2" ]
   then
25
   retval=$1
26
27
   else
   retval=$2
28
   fi
29
30 fi
31
                # Echoes (to stdout), rather than returning value.
32 echo $retval
33
                    # Why?
34 }
35
37 return_val=$(max2 33001 33997)
             ^^^^ Function name
38 #
               ^^^^ ^^^ Params passed
39 #
40 # This is actually a form of command substitution:
41 #+ treating a function as if it were a command,
42 #+ and assigning the stdout of the function to the variable "return_val."
43
44
46 if [ "$return_val" -eq "$E_PARAM_ERR" ]
47
   then
48
   echo "Error in parameters passed to comparison function!"
49 elif [ "$return_val" -eq "$EQUAL" ]
50 then
51 echo "The two numbers are equal."
52 else
53 echo "The larger of the two numbers is $return_val."
56
57 exit 0
58
59 # Exercises:
60 # ----
61 \# 1) Find a more elegant way of testing
```

```
62 #+ the parameters passed to the function.
63 # 2) Simplify the if/then structure at "OUTPUT."
64 # 3) Rewrite the script to take input from command-line parameters.
```

Here is another example of capturing a function "return value." Understanding it requires some knowledge of <u>awk</u>.

```
1 month_length () # Takes month number as an argument.
                   # Returns number of days in month.
3 monthD="31 28 31 30 31 30 31 31 30 31 30 31" # Declare as local?
4 echo "$monthD" | awk '{ print $'"${1}"' }' # Tricky.
6 # Parameter passed to function ($1 -- month number), then to awk.
7 # Awk sees this as "print $1 . . . print $12" (depending on month number)
8 # Template for passing a parameter to embedded awk script:
9 #
                                   $'"${script_parameter}"'
10
11 \# Needs error checking for correct parameter range (1-12)
12 #+ and for February in leap year.
13 }
14
15 # -----
16 # Usage example:
17 month=4 # April, for example (4th month).
18 days_in=$(month_length $month)
19 echo $days_in # 30
20 # -----
```

See also Example A-7.

Exercise: Using what we have just learned, extend the previous <u>Roman numerals example</u> to accept arbitrarily large input.

Redirection

Redirecting the stdin of a function

A function is essentially a <u>code block</u>, which means its stdin can be redirected (as in <u>Example 3-1</u>).

Example 23-11. Real name from username

```
1 #!/bin/bash
2 # realname.sh
 4 # From username, gets "real name" from /etc/passwd.
7 ARGCOUNT=1
               # Expect one arg.
8 E_WRONGARGS=65
10 file=/etc/passwd
11 pattern=$1
12
13 if [ $# -ne "$ARGCOUNT" ]
   echo "Usage: `basename $0` USERNAME"
16
    exit $E_WRONGARGS
17 fi
19 file_excerpt () # Scan file for pattern, then print relevant portion of line.
20 {
21 while read line # "while" does not necessarily need "[ condition ]"
```

```
23 echo "$\lim | grep $1 | awk -F":" '{ print $5 }' # Have awk use ":" delimiter.
24 done
25 } <\file # Redirect into function's stdin.
27 file_excerpt $pattern
28
29 # Yes, this entire script could be reduced to
         grep PATTERN /etc/passwd | awk -F":" '{ print $5 }'
30 #
31 # or
         awk -F: '/PATTERN/ {print $5}'
32 #
33 # or
34 #
        awk -F: '($1 == "username") { print $5 }' # real name from username
35 # However, it might not be as instructive.
37 exit 0
```

There is an alternate, and perhaps less confusing method of redirecting a function's stdin. This involves redirecting the stdin to an embedded bracketed code block within the function.

```
1 # Instead of:
 2 Function ()
 3 {
 4
    . . .
 5 } < file
 6
 7 # Try this:
 8 Function ()
 9 {
10
11
12 } < file
13 }
14
15 # Similarly,
16
17 Function () # This works.
18 {
19
20
     echo $*
21 } | trab
22 }
23
24 Function () # This doesn't work.
25 {
    echo $*
26
27 } | trab
              # A nested code block is mandatory here.
2.8
29
30 # Thanks, S.C.
```

Notes

[1] The **return** command is a Bash <u>builtin</u>.

 $\begin{tabular}{lllll} \hline Prev & Home & Next \\ \hline Process Substitution & Up & Local Variables \\ \hline & Advanced Bash-Scripting Guide: An in-depth exploration of the art of shell scripting \\ \hline Prev & Chapter 23. Functions & Next \\ \hline \end{tabular}$

23.2. Local Variables

What makes a variable *local*?

local variables

A variable declared as *local* is one that is visible only within the <u>block of code</u> in which it appears. It has local "scope." In a function, a *local variable* has meaning only within that function block.

Example 23-12. Local variable visibility

```
1 #!/bin/bash
 2 # Global and local variables inside a function.
 4 func ()
 5 {
   local loc_var=23
                           # Declared as local variable.
 7 echo
                           # Uses the 'local' builtin.
 8 echo "\"loc_var\" in function = $loc_var"
 9
   global_var=999
                           # Not declared as local.
10
                            # Defaults to global.
11 echo "\"global_var\" in function = $global_var"
12 }
13
14 func
15
16 # Now, to see if local variable "loc_var" exists outside function.
17
18 echo
19 echo "\"loc_var\" outside function = $loc_var"
2.0
                                         # $loc_var outside function =
21
                                         # No, $loc_var not visible globally.
22 echo "\"global_var\" outside function = $global_var"
                                         # $global_var outside function = 999
2.3
2.4
                                         # $global_var is visible globally.
25 echo
26
27 exit 0
28 # In contrast to C, a Bash variable declared inside a function
29 #+ is local *only* if declared as such.
```

Before a function is called, *all* variables declared within the function are invisible outside the body of the function, not just those explicitly declared as *local*.

```
1 #!/bin/bash
2
3 func ()
4 {
5 global_var=37
                 # Visible only within the function block
                   #+ before the function has been called.
7 }
                   # END OF FUNCTION
9 echo "global_var = $global_var" # global_var =
10
                                   # Function "func" has not yet been called,
11
                                   #+ so $global_var is not visible here.
12
13 func
14 echo "global_var = $global_var" # global_var = 37
                                    # Has been set by function call.
```

23.2.1. Local variables help make recursion possible.

Local variables permit recursion, [1] but this practice generally involves much computational overhead and is definitely *not* recommended in a shell script. [2]

Example 23-13. Recursion, using a local variable

```
1 #!/bin/bash
3 #
                 factorial
4 #
7 # Does bash permit recursion?
8 # Well, yes, but...
9 # It's so slow that you gotta have rocks in your head to try it.
10
11
12 MAX_ARG=5
13 E_WRONG_ARGS=65
14 E_RANGE_ERR=66
1.5
16
17 if [ -z "$1" ]
18 then
19 echo "Usage: `basename $0` number"
    exit $E_WRONG_ARGS
21 fi
23 if [ "$1" -gt $MAX_ARG ]
24 then
25 echo "Out of range (5 is maximum)."
26 # Let's get real now.
27 # If you want greater range than this,
28 #+ rewrite it in a Real Programming Language.
29 exit $E_RANGE_ERR
30 fi
31
32 fact ()
34 local number=$1
35 # Variable "number" must be declared as local,
36 #+ otherwise this doesn't work.
37 if [ "$number" -eq 0 ]
38 then
39 factorial=1 \# Factorial of 0 = 1.
40 else
    let "decrnum = number - 1"
41
     fact $decrnum # Recursive function call (the function calls itself).
42
     let "factorial = $number * $?"
43
44
45
46 return $factorial
47 }
48
49 fact $1
50 echo "Factorial of $1 is $?."
51
52 exit 0
```

See also Example A-16 for an example of recursion in a script. Be aware that recursion is resource-intensive and executes slowly, and is therefore generally not appropriate to use in a script.

Notes

- [1] <u>Herbert Mayer</u> defines recursion as "... expressing an algorithm by using a simpler version of that same algorithm . . . " A recursive function is one that calls itself.
- Too many levels of recursion may crash a script with a segfault. [2]

```
1 #!/bin/bash
3 # Warning: Running this script could possibly lock up your system!
4 # If you're lucky, it will segfault before using up all available memory.
6 recursive_function ()
7 {
8 echo "$1"
                # Makes the function do something, and hastens the segfault.
9 (($1 < $2)) && recursive_function $(($1 + 1)) $2;
10 # As long as 1st parameter is less than 2nd,
11 #+ increment 1st and recurse.
12 }
14 recursive_function 1 50000 # Recurse 50,000 levels!
15 # Most likely segfaults (depending on stack size, set by ulimit -m).
17 # Recursion this deep might cause even a C program to segfault,
18 #+ by using up all the memory allotted to the stack.
19
20
21 echo "This will probably not print."
22 exit 0 # This script will not exit normally.
23
24 # Thanks, Stéphane Chazelas.
```

Prev Chapter 23. Functions

23.3. Recursion Without Local Variables

A function may recursively call itself even without use of local variables.

Example 23-14. The Fibonacci Sequence

```
1 #!/bin/bash
 2 # fibo.sh : Fibonacci sequence (recursive)
 3 # Author: M. Cooper
 4 # License: GPL3
 7 \# Fibo(0) = 0
 8 \# Fibo(1) = 1
 9 # else
10 # Fibo(j) = Fibo(j-1) + Fibo(j-2)
11 # -----
12
13 MAXTERM=15  # Number of terms (+1) to generate.
14 MINIDX=2  # If idx is less than 2, then Fibo(
                  # If idx is less than 2, then Fibo(idx) = idx.
15
16 Fibonacci ()
17 {
    idx=$1 # Doesn't need to be local. Why not?
19 if [ "$idx" -lt "$MINIDX" ]
20 then
21
      echo "$idx" # First two terms are 0 1 ... see above.
22
   else
      (( --idx )) # j-1
23
2.4
      term1=$(Fibonacci $idx) # Fibo(j-1)
25
      (( --idx )) # j-2
26
     term2=$(Fibonacci $idx) # Fibo(j-2)
27
28
29
      echo $((term1 + term2))
30
    fi
31
    # An ugly, ugly kludge.
32
    # The more elegant implementation of recursive fibo in C
    \#+ is a straightforward translation of the algorithm in lines 7 - 10.
3.3
34 }
35
36 for i in $(seq 0 $MAXTERM)
37 do # Calculate $MAXTERM+1 terms.
38 FIBO=$(Fibonacci $i)
39 echo -n "$FIBO "
41 # 0 1 1 2 3 5 8 13 21 34 55 89 144 233 377 610
42 # Takes a while, doesn't it? Recursion in a script is slow.
43
44 echo
45
46 exit 0
```

Example 23-15. The Towers of Hanoi

```
1 #! /bin/bash
2 #
```

```
3 # The Towers Of Hanoi
4 # Bash script
5 # Copyright (C) 2000 Amit Singh. All Rights Reserved.
 6 # http://hanoi.kernelthread.com
7 #
8 # Tested under Bash version 2.05b.0(13)-release.
9 # Also works under Bash version 3.x.
10 #
11 # Used in "Advanced Bash Scripting Guide"
12 #+ with permission of script author.
13 # Slightly modified and commented by ABS author.
15 #=============#
16 \# The Tower of Hanoi is a mathematical puzzle attributed to
17 #+ Edouard Lucas, a nineteenth-century French mathematician.
18 #
19 # There are three vertical posts set in a base.
20 # The first post has a set of annular rings stacked on it.
21 # These rings are disks with a hole drilled out of the center,
22 #+ so they can slip over the posts and rest flat.
23 # The rings have different diameters, and they stack in ascending
24 #+ order, according to size.
25 \# The smallest ring is on top, and the largest on the bottom.
26 #
27 # The task is to transfer the stack of rings
28 #+ to one of the other posts.
29 # You can move only one ring at a time to another post.
30 # You are permitted to move rings back to the original post.
31 # You may place a smaller ring atop a larger one,
32 #+ but *not* vice versa.
33 # Again, it is forbidden to place a larger ring atop a smaller one.
34 #
35 # For a small number of rings, only a few moves are required.
36 #+ For each additional ring,
37 #+ the required number of moves approximately doubles,
38 #+ and the "strategy" becomes increasingly complicated.
39 #

Advanced Bash-Scripting Guide: An in-depth exploration of the art of shell scripting

<u>Prev</u> <u>Next</u>

Chapter 24. Aliases

A Bash *alias* is essentially nothing more than a keyboard shortcut, an abbreviation, a means of avoiding typing a long command sequence. If, for example, we include **alias lm="ls-l|more"** in the <u>~/.bashrc</u> <u>file</u>, then each **lm** typed at the command line will automatically be replaced by a **ls-l|more**. This can save a great deal of typing at the command line and avoid having to remember complex combinations of commands and options. Setting **alias rm="rm-i"** (interactive mode delete) may save a good deal of grief, since it can prevent inadvertently losing important files.

In a script, aliases have very limited usefulness. It would be quite nice if aliases could assume some of the functionality of the C preprocessor, such as macro expansion, but unfortunately Bash does not expand arguments within the alias body. [1] Moreover, a script fails to expand an alias itself within "compound constructs", such as <u>if/then</u> statements, loops, and functions. An added limitation is that an alias will not expand recursively. Almost invariably, whatever we would like an alias to do could be accomplished much more effectively with a <u>function</u>.

Example 24-1. Aliases within a script

```
1 #!/bin/bash
 2 # alias.sh
 4 shopt -s expand_aliases
 5 # Must set this option, else script will not expand aliases.
 8 # First, some fun.
 9 alias Jesse_James='echo "\"Alias Jesse James\" was a 1959 comedy starring Bob Hope."'
10 Jesse James
11
12 echo; echo; echo;
13
14 alias ll="ls -l"
15 # May use either single (') or double (") quotes to define an alias.
17 echo "Trying aliased \"ll\":"
18 ll /usr/X11R6/bin/mk* #* Alias works.
20 echo
2.1
22 directory=/usr/X11R6/bin/
23 prefix=mk* # See if wild card causes problems.
24 echo "Variables \"directory\" + \"prefix\" = $directory$prefix"
25 echo
27 alias lll="ls -l $directory$prefix"
29 echo "Trying aliased \"lll\":"
30 111 # Long listing of all files in /usr/X11R6/bin stating with mk.
31 # An alias can handle concatenated variables -- including wild card -- o.k.
33
34
35
36 TRUE=1
37
38 echo
40 if [ TRUE ]
```

```
41 then
42 alias rr="ls -l"
43 echo "Trying aliased \"rr\" within if/then statement:"
44 rr /usr/X11R6/bin/mk* #* Error message results!
45 # Aliases not expanded within compound statements.
46 echo "However, previously expanded alias still recognized:"
47 ll /usr/X11R6/bin/mk*
48 fi
49
50 echo
51
52 count=0
53 while [ $count -1t 3 ]
54 do
55 alias rrr="ls -l"
56
   echo "Trying aliased \"rrr\" within \"while\" loop:"
   rrr /usr/X11R6/bin/mk*  #* Alias will not expand here either.
                             # alias.sh: line 57: rrr: command not found
59 let count+=1
60 done
61
62 echo; echo
63
64 alias xyz='cat $0' # Script lists itself.
65
                      # Note strong quotes.
66 xyz
67 # This seems to work,
68 #+ although the Bash documentation suggests that it shouldn't.
70 # However, as Steve Jacobson points out,
71 \#+ the "$0" parameter expands immediately upon declaration of the alias.
72.
73 exit 0
```

The **unalias** command removes a previously set *alias*.

Example 24-2. unalias: Setting and unsetting an alias

```
1 #!/bin/bash
2 # unalias.sh
3
4 shopt -s expand_aliases # Enables alias expansion.
5

7 llm
8
9 echo
10
11 unalias llm # Unset alias.
12 llm
13 # Error message results, since 'llm' no longer recognized.
14
15 exit 0
```

```
bash$ ./unalias.sh

total 6

drwxrwxr-x 2 bozo bozo 3072 Feb 6 14:04 .

drwxr-xr-x 40 bozo bozo 2048 Feb 6 14:04 ..

-rwxr-xr-x 1 bozo bozo 199 Feb 6 14:04 unalias.sh

./unalias.sh: llm: command not found
```

Chapter 25. List Constructs

The "and list" and "or list" constructs provide a means of processing a number of commands consecutively. These can effectively replace complex nested **if/then** or even **case** statements.

Chaining together commands

and list

```
1 command-1 && command-2 && command-3 && ... command-n
```

Each command executes in turn provided that the previous command has given a return value of true (zero). At the first false (non-zero) return, the command chain terminates (the first command returning false is the last one to execute).

Example 25-1. Using an and list to test for command-line arguments

```
1 #!/bin/bash
 2 # "and list"
 4 if [ ! - z "$1" ] && echo "Argument #1 = $1" && [ ! - z "$2" ] \
 5 && echo "Argument #2 = $2"
 6 then
    echo "At least 2 arguments passed to script."
    # All the chained commands return true.
 9 else
10 echo "Less than 2 arguments passed to script."
11 # At least one of the chained commands returns false.
12 fi
13 # Note that "if [ ! -z $1 ]" works, but its supposed equivalent,
14 # if [ -n $1 ] does not.
15 # However, quoting fixes this.
16 # if [ -n "$1" ] works.
17 # Careful!
18 # It is always best to QUOTE tested variables.
19
21 # This accomplishes the same thing, using "pure" if/then statements.
22 if [ ! -z "$1" ]
23 then
24 echo "Argument #1 = $1"
25 fi
26 if [ ! -z "$2" ]
27 then
    echo "Argument #2 = $2"
    echo "At least 2 arguments passed to script."
30 else
31 echo "Less than 2 arguments passed to script."
33 # It's longer and less elegant than using an "and list".
34
35
36 exit 0
```

Example 25-2. Another command-line arg test using an and list

```
1 #!/bin/bash
2
3 ARGS=1  # Number of arguments expected.
4 E_BADARGS=65 # Exit value if incorrect number of args passed.
5
6 test $# -ne $ARGS && \
7 echo "Usage: `basename $0` $ARGS argument(s)" && exit $E_BADARGS
8 # If condition 1 tests true (wrong number of args passed to script),
9 #+ then the rest of the line executes, and script terminates.
10
11 # Line below executes only if the above test fails.
12 echo "Correct number of arguments passed to this script."
13
14 exit 0
15
16 # To check exit value, do a "echo $?" after script termination.
```

Of course, an *and list* can also *set* variables to a default value.

```
1 arg1=$@ && [ -z "$arg1" ] && arg1=DEFAULT
2
3  # Set $arg1 to command line arguments, if any.
4  # But . . . set to DEFAULT if not specified on command line.
```

or list

```
1 command-1 || command-2 || command-3 || ... command-n
```

Each command executes in turn for as long as the previous command returns false. At the first true return, the command chain terminates (the first command returning true is the last one to execute). This is obviously the inverse of the "and list".

Example 25-3. Using or lists in combination with an and list

```
1 #!/bin/bash
 3 # delete.sh, not-so-cunning file deletion utility.
4 # Usage: delete filename
 6 E_BADARGS=65
7
8 if [ -z "$1" ]
10 echo "Usage: `basename $0` filename"
11 exit $E_BADARGS # No arg? Bail out.
12 else
                    # Set filename.
13 file=$1
14 fi
15
17 [ ! -f "$file" ] && echo "File \"$file\" not found. \
18 Cowardly refusing to delete a nonexistent file."
19 # AND LIST, to give error message if file not present.
20 # Note echo message continued on to a second line with an escape.
22 [ ! -f "$file" ] || (rm -f $file; echo "File \"$file\" deleted.")
23 # OR LIST, to delete file if present.
2.4
25 # Note logic inversion above.
26 # AND LIST executes on true, OR LIST on false.
27
28 exit 0
```

1 If the first command in an "or list" returns true, it will execute.

```
1 # ==> The following snippets from the /etc/rc.d/init.d/single
 2 #+==> script by Miquel van Smoorenburg
 3 #+==> illustrate use of "and" and "or" lists.
 4 # ==> "Arrowed" comments added by document author.
 6 [ -x /usr/bin/clear ] && /usr/bin/clear
     # ==> If /usr/bin/clear exists, then invoke it.
     # ==> Checking for the existence of a command before calling it
 9
     #+==> avoids error messages and other awkward consequences.
10
11
     # ==> . . .
12
13 # If they want to run something in single user mode, might as well run it...
14 for i in /etc/rc1.d/S[0-9][0-9]*; do
          # Check if the script is there.
16
           [ -x "$i" ] || continue
17
     # ==> If corresponding file in $PWD *not* found,
     #+==> then "continue" by jumping to the top of the loop.
18
19
           # Reject backup files and files generated by rpm.
2.0
21
           case "$1" in
22
                   *.rpmsave|*.rpmorig|*.rpmnew|*~|*.orig)
2.3
                           continue;;
2.4
           [ "$i" = "/etc/rc1.d/S00single" ] && continue
     # ==> Set script name, but don't execute it yet.
2.6
2.7
           $i start
28 done
29
30
     # ==> . . .
```

! The exit status of an and list or an or list is the exit status of the last command executed.

Clever combinations of "and" and "or" lists are possible, but the logic may easily become convoluted and require close attention to operator precedence rules, and possibly extensive debugging.

```
1 false && true || echo false
                                       # false
 3 # Same result as
 4 (false && true) || echo false
                                       # false
 5 # But *not*
 6 false && ( true || echo false )
                                       # (nothing echoed)
 8 # Note left-to-right grouping and evaluation of statements,
 9 #+ since the logic operators "&&" and "||" have equal precedence.
10
11 # It's best to avoid such complexities, unless you know what you're doing.
12
13 # Thanks, S.C.
```

See Example A-7 and Example 7-4 for illustrations of using an **and / or list** to test variables.

Prev **Home** Next Aliases Up Arrays Advanced Bash-Scripting Guide: An in-depth exploration of the art of shell scripting <u>Prev</u> <u>Next</u>

Chapter 26. Arrays

Newer versions of Bash support one-dimensional arrays. Array elements may be initialized with the **variable**[xx] notation. Alternatively, a script may introduce the entire array by an explicit **declare** -a **variable** statement. To dereference (find the contents of) an array element, use *curly bracket* notation, that is, \${variable[xx]}.

Example 26-1. Simple array usage

```
1 #!/bin/bash
 4 area[11]=23
 5 area[13]=37
 6 area[51]=UFOs
 8 # Array members need not be consecutive or contiguous.
10 # Some members of the array can be left uninitialized.
11 # Gaps in the array are okay.
12 # In fact, arrays with sparse data ("sparse arrays")
13 #+ are useful in spreadsheet-processing software.
14
1.5
16 echo -n "area[11] = "
17 echo ${area[11]} # {curly brackets} needed.
19 echo -n "area[13] = "
20 echo ${area[13]}
22 echo "Contents of area[51] are ${area[51]}."
24 # Contents of uninitialized array variable print blank (null variable).
25 \text{ echo -n "area}[43] = "
26 echo ${area[43]}
27 echo "(area[43] unassigned)"
28
29 echo
30
31 # Sum of two array variables assigned to third
32 area[5]=`expr ${area[11]} + ${area[13]}`
33 echo "area[5] = area[11] + area[13]"
34 echo -n "area[5] = "
35 echo ${area[5]}
37 area[6]=`expr ${area[11]} + ${area[51]}`
38 echo "area[6] = area[11] + area[51]"
39 echo -n "area[6] = "
40 echo ${area[6]}
41 # This fails because adding an integer to a string is not permitted.
43 echo; echo; echo
44
45 # -----
46 # Another array, "area2".
47 # Another way of assigning array variables...
48 # array_name=( XXX YYY ZZZ ...)
50 area2=( zero one two three four )
```

```
51
52 \text{ echo } -n \text{ "area2[0]} = \text{"}
53 echo ${area2[0]}
54 # Aha, zero-based indexing (first element of array is [0], not [1]).
56 echo -n "area2[1] = "
57 echo \{area2[1]\} # [1] is second element of array.
59
60 echo; echo; echo
61
62 # -----
63 # Yet another array, "area3".
64 # Yet another way of assigning array variables...
65 # array_name=([xx]=XXX [yy]=YYY ...)
67 area3=([17]=seventeen [24]=twenty-four)
68
69 echo -n "area3[17] = "
70 echo ${area3[17]}
71
72 \text{ echo } -n \text{ "area3}[24] = \text{"}
73 echo ${area3[24]}
74 # ----
75
76 exit 0
```

As we have seen, a convenient way of initializing an entire array is the array= (element1 element2 ... elementN) notation.

```
Bash permits array operations on variables, even if the variables are not explicitly declared as arrays.
```

```
1 string=abcABC123ABCabc
   2 echo ${string[@]}
                                       # abcABC123ABCabc
   3 echo ${string[*]}
                                       # abcABC123ABCabc
   4 echo ${string[0]}
                                       # abcABC123ABCabc
   5 echo ${string[1]}
                                       # No output!
                                       # Why?
   7 echo ${#string[@]}
                                       # 1
   8
                                       # One element in the array.
   9
                                       # The string itself.
  10
  11 # Thank you, Michael Zick, for pointing this out.
Once again this demonstrates that <u>Bash variables are untyped</u>.
```

Example 26-2. Formatting a poem

```
1 #!/bin/bash
2 # poem.sh: Pretty-prints one of the document author's favorite poems.
3
4 # Lines of the poem (single stanza).
5 Line[1]="I do not know which to prefer,"
6 Line[2]="The beauty of inflections"
7 Line[3]="Or the beauty of innuendoes,"
8 Line[4]="The blackbird whistling"
9 Line[5]="Or just after."
10
```

```
11 # Attribution.
 12 Attrib[1]=" Wallace Stevens"
 13 Attrib[2]="\"Thirteen Ways of Looking at a Blackbird\""
14 # This poem is in the Public Domain (copyright expired).
16 echo
17
18 for index in 1 2 3 4 5  # Five lines.
19 do
 20 printf " %s\n" "${Line[index]}"
 21 done
 2.2.
 23 for index in 1 2  # Two attribution lines.
 24 do
 25 printf " %s\n" "${Attrib[index]}"
 26 done
 27
 28 echo
 29
 30 exit 0
 31
 32 # Exercise:
 33 # -----
34 # Modify this script to pretty-print a poem from a text data file.
```

Array variables have a syntax all their own, and even standard Bash commands and operators have special options adapted for array use.

Example 26-3. Various array operations

```
1 #!/bin/bash
 2 # array-ops.sh: More fun with arrays.
 5 array=( zero one two three four five )
 6 # Element 0 1 2 3 4 5
                        # zero
 8 echo ${array[0]}
 9 echo ${array:0}
                        # zero
10
                        # Parameter expansion of first element,
                        #+ starting at position # 0 (1st character).
11
                        # ero
12 echo ${array:1}
1.3
                         # Parameter expansion of first element,
14
                         #+ starting at position # 1 (2nd character).
15
16 echo "----"
17
18 echo ${#array[0]}
                        # 4
                         # Length of first element of array.
20 echo ${#array}
                         # 4
                         # Length of first element of array.
21
22
                         # (Alternate notation)
23
24 echo ${#array[1]}
25
                         # Length of second element of array.
26
                         # Arrays in Bash have zero-based indexing.
27
28 echo ${#array[*]}
                         #
                           Number of elements in array.
30 echo ${#array[@]}
31
                         # Number of elements in array.
32
```

Many of the standard string operations work on arrays.

Example 26-4. String operations on arrays

```
1 #!/bin/bash
2 # array-strops.sh: String operations on arrays.
3 # Script by Michael Zick.
 4 # Used with permission.
 6 # In general, any string operation in the ${name ...} notation
 7 #+ can be applied to all string elements in an array
8 #+ with the \{name[@] ...\} or \{name[*] ...\} notation.
10
11 arrayZ=( one two three four five five)
12
13 echo
14
15 # Trailing Substring Extraction
16 echo ${arrayZ[@]:0} # one two three four five five
17
                           # All elements.
18
                           # two three four five five
19 echo ${arrayZ[@]:1}
                           # All elements following element[0].
2.1
22 echo ${arrayZ[@]:1:2}
                          # two three
23
                           # Only the two elements after element[0].
24
25 echo "-----"
2.6
27 # Substring Removal
28 # Removes shortest match from front of string(s),
29 #+ where the substring is a regular expression.
                          # one two three five five
31 echo ${arrayZ[@]#f*r}
32
                           # Applied to all elements of the array.
33
                           # Matches "four" and removes it.
34
35 # Longest match from front of string(s)
36 echo ${arrayZ[@]##t*e} # one two four five five
37
                           # Applied to all elements of the array.
38
                           # Matches "three" and removes it.
39
40 # Shortest match from back of string(s)
41 echo ${arrayZ[@]%h*e} # one two t four five five
42
                           # Applied to all elements of the array.
43
                           # Matches "hree" and removes it.
44
45 # Longest match from back of string(s)
```

```
46 echo ${arrayZ[@]%%t*e} # one two four five five
                           # Applied to all elements of the array.
                           # Matches "three" and removes it.
48
49
50 echo "-----"
52 # Substring Replacement
53
54 # Replace first occurance of substring with replacement
55 echo ${arrayZ[@]/fiv/XYZ} # one two three four XYZe XYZe
56
                               # Applied to all elements of the array.
57
58 # Replace all occurances of substring
59 echo ${arrayZ[@]//iv/YY} # one two three four fYYe fYYe
60
                               # Applied to all elements of the array.
61
62 # Delete all occurances of substring
63 # Not specifing a replacement means 'delete'
64 echo {arrayZ[@]//fi/} # one two three four ve ve
65
                               # Applied to all elements of the array.
66
67 # Replace front-end occurances of substring
68 echo ${arrayZ[@]/#fi/XY} # one two three four XYve XYve
69
                               # Applied to all elements of the array.
70
71 # Replace back-end occurances of substring
72 echo ${arrayZ[@]/%ve/ZZ} # one two three four fiZZ fiZZ
                               # Applied to all elements of the array.
74
75 echo ${arrayZ[@]/%o/XX}
                             # one twXX three four five five
76
                               # Why?
77
78 echo "----"
79
80
81 # Before reaching for awk (or anything else) --
82 # Recall:
      $( ... ) is command substitution.
      Functions run as a sub-process.
85 # Functions write their output to stdout.
86 # Assignment reads the function's stdout.
87 \# The name[@] notation specifies a "for-each" operation.
88
89 newstr() {
90 echo -n "!!!"
91 }
93 echo ${arrayZ[@]/%e/$(newstr)}
94 # on!!! two thre!!! four fiv!!! fiv!!!
95 # Q.E.D: The replacement action is an 'assignment.'
97 # Accessing the "For-Each"
98 echo ${arrayZ[@]//*/$(newstr optional_arguments)}
99 \# Now, if Bash would just pass the matched string as \$0
100 \#+ to the function being called . . .
101
102 echo
103
104 exit 0
```

<u>Command substitution</u> can construct the individual elements of an array.

```
1 #!/bin/bash
2 # script-array.sh: Loads this script into an array.
3 # Inspired by an e-mail from Chris Martin (thanks!).
5 script_contents=( $(cat "$0") ) # Stores contents of this script ($0)
                                   #+ in an array.
7
8 for element in $(seq 0 $((${#script_contents[@]} - 1)))
                       # ${#script_contents[@]}
9 do
10
                       #+ gives number of elements in the array.
11
12
                         Question:
                         Why is seq 0 necessary?
13
14
                       # Try changing it to seq 1.
15 echo -n "${script_contents[$element]}"
                       # List each field of this script on a single line.
16
                    # Use " -- " as a field separator.
17 echo -n " -- "
18 done
19
20 echo
21
22 exit 0
23
24 # Exercise:
25 # -----
26 # Modify this script so it lists itself
27 #+ in its original format,
28 #+ complete with whitespace, line breaks, etc.
```

In an array context, some Bash <u>builtins</u> have a slightly altered meaning. For example, <u>unset</u> deletes array elements, or even an entire array.

Example 26-6. Some special properties of arrays

```
1 #!/bin/bash
3 declare -a colors
4 # All subsequent commands in this script will treat
 5 #+ the variable "colors" as an array.
7 echo "Enter your favorite colors (separated from each other by a space)."
                   # Enter at least 3 colors to demonstrate features below.
9 read -a colors
10 # Special option to 'read' command,
11 #+ allowing assignment of elements in an array.
12
13 echo
14
15 element_count=${#colors[@]}
16 # Special syntax to extract number of elements in array.
17 #
       element_count=${#colors[*]} works also.
18 #
19 \# The "0" variable allows word splitting within quotes
20 #+ (extracts variables separated by whitespace).
22 \# This corresponds to the behavior of "$@" and "$*"
23 #+ in positional parameters.
25 index=0
27 while [ "$index" -lt "$element_count" ]
28 do # List all the elements in the array.
```

```
echo ${colors[$index]}
30 let "index = $index + 1"
31 # Or:
32 \# index+=1
33 # if running Bash, version 3.1 or later.
35 # Each array element listed on a separate line.
36 # If this is not desired, use echo -n "${colors[$index]} "
37 #
38 # Doing it with a "for" loop instead:
39 # for i in "${colors[@]}"
40 #
      echo "$i"
41 #
42 # done
43 # (Thanks, S.C.)
45 echo
46
47 # Again, list all the elements in the array, but using a more elegant method.
   echo ${colors[@]} # echo ${colors[*]} also works.
48
49
50 echo
51
52 # The "unset" command deletes elements of an array, or entire array.
53 unset colors[1] # Remove 2nd element of array.
                              # Same effect as colors[1]=
55 echo ${colors[@]}
                              # List array again, missing 2nd element.
57 unset colors
                              # Delete entire array.
58
                              # unset colors[*] and
59
                              #+ unset colors[@] also work.
60 echo; echo -n "Colors gone."
61 echo ${colors[@]}
                              # List array again, now empty.
62
63 exit 0
```

As seen in the previous example, either \$\{\array_name[@]\}\ or \$\{\array_name[*]\}\ refers to \all the elements of the array. Similarly, to get a count of the number of elements in an array, use either \$\{\array_name[@]\}\ or \$\{\array_name[*]\}\. \$\{\array_name[0]\}\, the first element of the array.

Example 26-7. Of empty arrays and empty elements

```
1 #!/bin/bash
 2 # empty-array.sh
 4 # Thanks to Stephane Chazelas for the original example,
 5 #+ and to Michael Zick and Omair Eshkenazi for extending it.
 8 # An empty array is not the same as an array with empty elements.
10
   array0=( first second third )
11 array1=( '' ) \# "array1" consists of one empty element.
                    # No elements . . . "array2" is empty.
12
   array2=()
13 array3=( )
                   # What about this array?
14
15 echo
16 ListArray()
17 {
```

```
18 echo
19 echo "Elements in array0: ${array0[@]}"
20 echo "Elements in array1: ${array1[@]}"
21 echo "Elements in array2: ${array2[@]}"
22 echo "Elements in array3: ${array3[@]}"
24 echo "Length of first element in array0 = ${#array0}"
25 echo "Length of first element in array1 = ${#array1}"
26 echo "Length of first element in array2 = ${#array2}"
27 echo "Length of first element in array3 = ${#array3}"
28 echo
29 echo "Number of elements in array0 = \{\#array0[*]\}" # 3
30 echo "Number of elements in array1 = ${#array1[*]}" # 1
                                                           (Surprise!)
31 echo "Number of elements in array2 = ${#array2[*]}" # 0
32 echo "Number of elements in array3 = ${#array3[*]}"
34
36
37 ListArray
38
39 # Try extending those arrays.
40
41 # Adding an element to an array.
42 array0=( "${array0[@]}" "new1" )
43 array1=( "${array1[@]}" "new1" )
44 array2=( "${array2[@]}" "new1" )
45 array3=( "${array3[@]}" "new1" )
47 ListArray
48
49 # or
50 array0[${#array0[*]}]="new2"
51 array1[${#array1[*]}]="new2"
52 array2[${#array2[*]}]="new2"
53 array3[${#array3[*]}]="new2"
54
55 ListArray
56
57 # When extended as above; arrays are 'stacks'
58 # The above is the 'push'
59 # The stack 'height' is:
60 height=${#array2[@]}
61 echo
62 echo "Stack height for array2 = $height"
63
64 # The 'pop' is:
65 unset array2[${#array2[@]}-1] # Arrays are zero-based,
                                 #+ which means first element has index 0.
66 height=${#array2[@]}
67 echo
68 echo "POP"
69 echo "New stack height for array2 = $height"
70
71 ListArray
72
73 # List only 2nd and 3rd elements of array0.
74 from=1
                     # Zero-based numbering.
75 to=2
76 array3=( ${array0[@]:1:2} )
78 echo "Elements in array3: ${array3[@]}"
79
80 # Works like a string (array of characters).
81 # Try some other "string" forms.
82
83 # Replacement:
```

```
84 array4=( ${array0[@]/second/2nd} )
 85 echo
86 echo "Elements in array4: ${array4[@]}"
87
88 # Replace all matching wildcarded string.
89 array5=( ${array0[@]//new?/old} )
 90 echo
 91 echo "Elements in array5: ${array5[@]}"
 92
 93 \# Just when you are getting the feel for this . . .
 94 array6=( ${array0[@] #*new} )
 95 echo # This one might surprise you.
96 echo "Elements in array6: ${array6[@]}"
 97
98 array7=( ${array0[@]#new1} )
99 echo # After array6 this should not be a surprise.
100 echo "Elements in array7: ${array7[@]}"
101
102 # Which looks a lot like . . .
103 array8=( ${array0[@]/new1/} )
104 echo
105 echo "Elements in array8: ${array8[@]}"
106
107 # So what can one say about this?
108
109 # The string operations are performed on
110 #+ each of the elements in var[@] in succession.
111 # Therefore : Bash supports string vector operations
112 #+ if the result is a zero length string,
113 #+ that element disappears in the resulting assignment.
114
115 # Question, are those strings hard or soft quotes?
116
117 zap='new*'
118 array9=( ${array0[@]/$zap/} )
119 echo
120 echo "Elements in array9: ${array9[@]}"
122 # Just when you thought you where still in Kansas . . .
123 array10=( ${array0[@]#$zap} )
124 echo
125 echo "Elements in array10: ${array10[@]}"
126
127 # Compare array7 with array10.
128 # Compare array8 with array9.
129
130 # Answer: must be soft quotes.
131
132 exit 0
```

The relationship of **\${array_name[@]}** and **\${array_name[*]}** is analogous to that between <u>\$@ and \$*</u>. This powerful array notation has a number of uses.

The array=(element1 element2 ... elementN) initialization operation, with the help of <u>command</u> <u>substitution</u>, makes it possible to load the contents of a text file into an array.

```
1 #!/bin/bash
3 filename=sample_file
4
5 #
              cat sample_file
 6 #
 7 #
               1 a b c
8 #
                2 d e fg
9
10
11 declare -a array1
12
13 array1=( `cat "$filename"`)  # Loads contents
14 # List file to stdout  #+ of $filename into array1.
15 #
16 # array1=( `cat "$filename" | tr '\n' ' '`)
                                change linefeeds in file to spaces.
18 # Not necessary because Bash does word splitting,
19 #+ changing linefeeds to spaces.
2.0
21 echo ${array1[@]}
                                # List the array.
22 #
                                 1 a b c 2 d e fg
23 #
24 # Each whitespace-separated "word" in the file
25 #+ has been assigned to an element of the array.
27 element_count=${#array1[*]}
28 echo $element_count
```

Clever scripting makes it possible to add array operations.

Example 26-8. Initializing arrays

```
1 #! /bin/bash
2 # array-assign.bash
3
4 # Array operations are Bash-specific,
5 #+ hence the ".bash" in the script name.
6
7 # Copyright (c) Michael S. Zick, 2003, All rights reserved.
8 # License: Unrestricted reuse in any form, for any purpose.
9 # Version: $ID$
10 #
```

```
11 # Clarification and additional comments by William Park.
12
13 # Based on an example provided by Stephane Chazelas
14 #+ which appeared in the book: Advanced Bash Scripting Guide.
16 # Output format of the 'times' command:
17 # User CPU <space> System CPU
18 # User CPU of dead children <space> System CPU of dead children
19
20 # Bash has two versions of assigning all elements of an array
21 #+ to a new array variable.
22 # Both drop 'null reference' elements
23 #+ in Bash versions 2.04, 2.05a and 2.05b.
24 # An additional array assignment that maintains the relationship of
25 #+ [subscript]=value for arrays may be added to newer versions.
27 # Constructs a large array using an internal command,
28 #+ but anything creating an array of several thousand elements
29 #+ will do just fine.
30
31 declare -a bigOne=( /\text{dev}/* ) # All the files in /\text{dev} . .
33 echo 'Conditions: Unquoted, default IFS, All-Elements-Of'
34 echo "Number of elements in array is ${\#bigOne[@]}"
36 # set -vx
37
38
39
40 echo
41 echo '- - testing: =( ${array[@]} ) - -'
42 times
43 declare -a bigTwo=( ${bigOne[@]} )
44 # Note parens:
45 times
46
47
48 echo
49 echo '- - testing: =${array[@]} - -'
50 times
51 declare -a bigThree=${bigOne[@]}
52 # No parentheses this time.
53 times
54
55 # Comparing the numbers shows that the second form, pointed out
56 #+ by Stephane Chazelas, is from three to four times faster.
58 # As William Park explains:
59 #+ The bigTwo array assigned element by element (because of parentheses),
60 #+ whereas bigThree assigned as a single string.
61 # So, in essence, you have:
62 #
                       bigTwo=( [0]="..." [1]="..." [2]="..." ... )
63 #
                       bigThree=( [0]="... ... )
64 #
65 # Verify this by: echo ${bigTwo[0]}
66 #
                       echo ${bigThree[0]}
67
68
69 # I will continue to use the first form in my example descriptions
70 #+ because I think it is a better illustration of what is happening.
72 # The reusable portions of my examples will actual contain
73 #+ the second form where appropriate because of the speedup.
75 # MSZ: Sorry about that earlier oversight folks.
```

```
77
78 # Note:
79 # ---
80 \# The "declare -a" statements in lines 31 and 43
81 #+ are not strictly necessary, since it is implicit
82 #+ in the Array=( ... ) assignment form.
83 # However, eliminating these declarations slows down
84 #+ the execution of the following sections of the script.
85 # Try it, and see.
87 exit 0
```

(Adding a superfluous declare -a statement to an array declaration may speed up execution of subsequent operations on the array.

Example 26-9. Copying and concatenating arrays

```
1 #! /bin/bash
2 # CopyArray.sh
3 #
4 # This script written by Michael Zick.
5 # Used here with permission.
7 # How-To "Pass by Name & Return by Name"
8 #+ or "Building your own assignment statement".
10
11 CpArray_Mac() {
12
13 # Assignment Command Statement Builder
1 4
      echo -n 'eval '
1.5
     echo -n "$2"
16
                                     # Destination name
      echo -n '=( ${'
17
18
      echo -n "$1"
                                      # Source name
19
      echo -n '[@]} )'
20
21 # That could all be a single command.
22 # Matter of style only.
23 }
24
                                     # Function "Pointer"
25 declare -f CopyArray
                                     # Statement Builder
26 CopyArray=CpArray_Mac
27
28 Hype()
29 {
30
31 # Hype the array named $1.
32 # (Splice it together with array containing "Really Rocks".)
33 # Return in array named $2.

--

Arrays permit deploying old familiar algorithms as shell scripts. Whether this is necessarily a good idea is left to the reader to decide.

Example 26-11. The Bubble Sort

```
1 #!/bin/bash
 2 # bubble.sh: Bubble sort, of sorts.
 4 # Recall the algorithm for a bubble sort. In this particular version...
 6 # With each successive pass through the array to be sorted,
 7 #+ compare two adjacent elements, and swap them if out of order.
 8 # At the end of the first pass, the "heaviest" element has sunk to bottom.
 9 # At the end of the second pass, the next "heaviest" one has sunk next to bottom.
10 # And so forth.
11 # This means that each successive pass needs to traverse less of the array.
12 # You will therefore notice a speeding up in the printing of the later passes.
13
14
15 exchange()
16 {
17
     # Swaps two members of the array.
18 local temp=${Countries[$1]} # Temporary storage
                                #+ for element getting swapped out.
19
21 Countries[$2]=$temp
2.2.
23
    return
24 }
25
26 declare -a Countries # Declare array,
                        #+ optional here since it's initialized below.
29 # Is it permissable to split an array variable over multiple lines
30 #+ using an escape (\)?
31 # Yes.
32
33 Countries=(Netherlands Ukraine Zaire Turkey Russia Yemen Syria \
34 Brazil Argentina Nicaragua Japan Mexico Venezuela Greece England \
35 Israel Peru Canada Oman Denmark Wales France Kenya \
36 Xanadu Qatar Liechtenstein Hungary)
38 # "Xanadu" is the mythical place where, according to Coleridge,
39 #+ Kubla Khan did a pleasure dome decree.
40
41
42 clear

Is it possible to nest arrays within arrays?

```
10
 11 # Spaces are significant . . . and don't quote anything in the above.
 12
 13 SubArray=( ${AnArray[@]:11:1} ${AnArray[@]:6:5} )
 14 # This array has six elements:
 15 #+ SubArray=([0]=${AnArray[11]} [1]=${AnArray[6]} [2]=${AnArray[7]}
 16 #
          [3]=${AnArray[8]} [4]=${AnArray[9]} [5]=${AnArray[10]} )
 17 #
 18 # Arrays in Bash are (circularly) linked lists
 19 #+ of type string (char *).
 20 # So, this isn't actually a nested array,
 21 #+ but it's functionally similar.
 23 echo "Current directory and date of last status change:"
 24 echo "${SubArray[@]}"
26 exit 0
```

Embedded arrays in combination with indirect references create some fascinating possibilities

Example 26-12. Embedded arrays and indirect references

```
1 #!/bin/bash
 2 # embedded-arrays.sh
 3 # Embedded arrays and indirect references.
 5 # This script by Dennis Leeuw.
 6 # Used with permission.
7 # Modified by document author.
8
9
10 ARRAY1=(
11 VAR1_1=value11
12.
         VAR1_2=value12
13
         VAR1_3=value13
14)
15
16 ARRAY2=(
17 VARIABLE="test"
         STRING="VAR1=value1 VAR2=value2 VAR3=value3"
18
19
         ARRAY21=${ARRAY1[*]}
20)
         # Embed ARRAY1 within this second array.
21
22 function print () {
OLD_IFS="$IFS"
                          # To print each array element
2.4
          IFS=$'\n'
25
                          #+ on a separate line.
26
         TEST1="ARRAY2[*]"
         local ${!TEST1} # See what happens if you delete this line.
2.7
28
         # Indirect reference.
29 # This makes the components of $TEST1
30 #+ accessible to this function.
31
32
33
          # Let's see what we've got so far.
34
          echo
         echo "\$TEST1 = $TEST1" # Just the name of the variable.
35
36
          echo; echo
37
          echo "{\$TEST1} = ${!TEST1}" # Contents of the variable.
38
                                       # That's what an indirect
39
                                       #+ reference does.
```

```
40
         echo

56
          local ${!TEST2} # Indirect reference (as above).
57
          echo "Array element VAR1_1: $VAR1_1 from ARRAY21"
58 }
59
60 print
61 echo
62
63 exit 0
64
65 # As the author of the script notes,
66 #+ "you can easily expand it to create named-hashes in bash."
67 # (Difficult) exercise for the reader: implement this.
```

Arrays enable implementing a shell script version of the *Sieve of Eratosthenes*. Of course, a resource-intensive application of this nature should really be written in a compiled language, such as C. It runs excruciatingly slowly as a script.

Example 26-13. The Sieve of Eratosthenes

```
1 #!/bin/bash
2 # sieve.sh (ex68.sh)
4 # Sieve of Eratosthenes
 5 # Ancient algorithm for finding prime numbers.
7 # This runs a couple of orders of magnitude slower
8 #+ than the equivalent program written in C.
10 LOWER_LIMIT=1
                       # Starting with 1.
11 UPPER_LIMIT=1000  # Up to 1000.
12 # (You may set this higher . . . if you have time on your hands.)
13
14 PRIME=1
15 NON_PRIME=0
16
17 let SPLIT=UPPER_LIMIT/2
18 # Optimization:
19 # Need to test numbers only halfway to upper limit (why?).
20
21
22 declare -a Primes
23 # Primes[] is an array.
24
```

```
25
26 initialize ()
27 {
28 # Initialize the array.
30 i=$LOWER_LIMIT
31 until [ "$i" -gt "$UPPER_LIMIT" ]
33 Primes[i]=$PRIME
34 let "i += 1"
35 done
36 # Assume all array members guilty (prime)
37 #+ until proven innocent.
38 }
39
40 print_primes ()
41 {
42 # Print out the members of the Primes[] array tagged as prime.
43
44 i=$LOWER_LIMIT
4.5
46 until [ "$i" -gt "$UPPER_LIMIT" ]
47 do
48
49 if [ "${Primes[i]}" -eq "$PRIME" ]
50 then
     printf "%8d" $i
51
      # 8 spaces per number gives nice, even columns.
53 fi
54
55 let "i += 1"
56
57 done
58
59 }
61 sift () # Sift out the non-primes.
62 {
64 let i=$LOWER_LIMIT+1
65 # We know 1 is prime, so let's start with 2.
67 until [ "$i" -gt "$UPPER_LIMIT" ]
68 do
69
70 if [ "${Primes[i]}" -eq "$PRIME" ]
71 # Don't bother sieving numbers already sieved (tagged as non-prime).
72 then
73
74
   t=$i
75
76 while [ "$t" -le "$UPPER_LIMIT" ]
77
     let "t += $i "

33 printf "%8d" ${Primes[*]}
34 echo; echo
36 exit $?
```

Compare these array-based prime number generators with an alternative that does not use arrays, <u>Example A-16</u>.

--

Arrays lend themselves, to some extent, to emulating data structures for which Bash has no native support.

Example 26-15. Emulating a push-down stack

```
1 #!/bin/bash
 2 # stack.sh: push-down stack simulation
 4 # Similar to the CPU stack, a push-down stack stores data items
 5 #+ sequentially, but releases them in reverse order, last-in first-out.
 7 BP=100
                     # Base Pointer of stack array.
 8
                     # Begin at element 100.
 9
10 SP=$BP
                    # Stack Pointer.
                     # Initialize it to "base" (bottom) of stack.
11
12
13 Data=
                     # Contents of stack location.
                     # Must use global variable,
14
                    #+ because of limitation on function return range.
15
16
17 declare -a stack
18
19
20 push()
                   # Push item on stack.
21 {
22 if [ -z "$1" ] # Nothing to push?
23 then
24 return
25 fi
2.6
27 let "SP -= 1"
                    # Bump stack pointer.
28 stack[$SP]=$1
29
30 return
```

```
31 }
32
                       # Pop item off stack.
33 pop()
34 {
35 Data=
                       # Empty out data item.
37 if [ "$SP" -eq "$BP" ]  # Stack empty?
38 then
39 return
40 fi
                       # This also keeps SP from getting past 100,
41
                        #+ i.e., prevents a runaway stack.
42
43 Data=${stack[$SP]}
44 let "SP += 1"
                       # Bump stack pointer.
45 return
46 }
47
                 # Find out what's happening.
48 status_report()
49 {
50 echo "-----"
51 echo "REPORT"
52 echo "Stack Pointer = $SP"
53 echo "Just popped \""$Data"\" off the stack."
54 echo "-----
55 echo
56 }
57
60 # Now, for some fun.
61
62 echo
63
64 # See if you can pop anything off empty stack.
66 status_report
67
68 echo
69
70 push garbage
71 pop
72 status_report  # Garbage in, garbage out.
73

75 value2=skidoo; push $value2
76 value3=FINAL; push $value3
77
78 pop
               # FINAL
79 status_report
80 pop
                # skidoo
81 status_report
               # 23
82 pop
83 status_report  # Last-in, first-out!
84
85 \# Notice how the stack pointer decrements with each push,
86 #+ and increments with each pop.
87
88 echo
89
90 exit 0
91
93
94
95 # Exercises:
96 # -----
```

```
97
98 # 1) Modify the "push()" function to permit pushing
99 # + multiple element on the stack with a single function call.

100
101 # 2) Modify the "pop()" function to permit popping
102 # + multiple element from the stack with a single function call.

103
104 # 3) Add error checking to the critical functions.
105 # That is, return an error code, depending on
106 # + successful or unsuccessful completion of the operation,
107 # + and take appropriate action.

108
109 # 4) Using this script as a starting point,
110 # + write a stack-based 4-function calculator.
```

--

Fancy manipulation of array "subscripts" may require intermediate variables. For projects involving this, again consider using a more powerful programming language, such as Perl or C.

Example 26-16. Complex array application: Exploring a weird mathematical series

```
1 #!/bin/bash
 3 # Douglas Hofstadter's notorious "Q-series":
 5 \# Q(1) = Q(2) = 1
 6 \# Q(n) = Q(n - Q(n-1)) + Q(n - Q(n-2)), \text{ for } n>2
 8 # This is a "chaotic" integer series with strange
 9 #+ and unpredictable behavior.
10 # The first 20 terms of the series are:
11 # 1 1 2 3 3 4 5 5 6 6 6 8 8 8 10 9 10 11 11 12
13 # See Hofstadter's book, _Goedel, Escher, Bach: An Eternal Golden Braid_,
14 #+ p. 137, ff.
15
16
17 LIMIT=100 # Number of terms to calculate.
18 LINEWIDTH=20 # Number of terms printed per line.
19
20 0[1]=1
               # First two terms of series are 1.
21 Q[2]=1
2.2.
23 echo
24 echo "Q-series [$LIMIT terms]:"
25 echo -n "\{Q[1]\}" # Output first two terms.
26 echo -n "${Q[2]}
28 for ((n=3; n \le \text{$LIMIT}; n++)) \# C-like loop expressions.
29 do \# Q[n] = Q[n - Q[n-1]] + Q[n - Q[n-2]] for n>2
       Need to break the expression into intermediate terms,
31 #+ since Bash doesn't handle complex array arithmetic very well.
32
    let "n1 = $n - 1"
33
                            # n-1
    let "n2 = $n - 2"
34
                             # n-2
35
    t0=`expr $n - ${Q[n1]}` # n - Q[n-1]
36
37
    t1=`expr n - \{Q[n2]\}` # n - Q[n-2]
38
                             \# Q[n - Q[n-1]]
39 T0=\$\{Q[t0]\}
40 T1=\$\{Q[t1]\}
                            \# Q[n - Q[n-2]]
```

```
41
42 Q[n]=`expr $T0 + $T1`
                            \# Q[n - Q[n-1]] + Q[n - Q[n-2]]
43 echo -n "${Q[n]} "
45 if [ `expr $n % $LINEWIDTH` -eq 0 ] # Format output.
46 then # ^ modulo
47 echo # Break lines into neat chunks.
48 fi
49
50 done
51
52 echo
53
54 exit 0
55
56 # This is an iterative implementation of the Q-series.
     The more intuitive recursive implementation is left as an exercise.
58 # Warning: calculating this series recursively takes a VERY long time
59 #+ via a script. C/C++ would be more suitable.
```

--

Bash supports only one-dimensional arrays, though a little trickery permits simulating multi-dimensional ones.

Example 26-17. Simulating a two-dimensional array, then tilting it

```
1 #!/bin/bash
2 # twodim.sh: Simulating a two-dimensional array.
4 # A one-dimensional array consists of a single row.
5 # A two-dimensional array stores rows sequentially.
7 Rows=5
8 Columns=5
9 # 5 X 5 Array.
10
11 declare -a alpha
                       # char alpha [Rows] [Columns];
12
                        # Unnecessary declaration. Why?
13
14 load_alpha ()
15 {
16 local rc=0
17 local index
18
19 for i in A B C D E F G H I J K L M N O P Q R S T U V W X Y
20 do # Use different symbols if you like.
21 local row=`expr $rc / $Columns`
22 local column=`expr $rc % $Rows`
23 let "index = $row * $Rows + $column"
24 alpha[$index]=$i
25 # alpha[$row][$column]
26 let "rc += 1"
27 done
2.8
29 # Simpler would be
30 #+ declare -a alpha=( A B C D E F G H I J K L M N O P Q R S T U V W X Y )
31 #+ but this somehow lacks the "flavor" of a two-dimensional array.
32 }
33
34 print_alpha ()
```

```
35 {
36 local row=0
37 local index
39 echo
41 while [ "$row" -lt "$Rows" ] # Print out in "row major" order:
                                  #+ columns vary,
43
                                  #+ while row (outer loop) remains the same.
44
    local column=0
4.5
    echo -n "
                                  # Lines up "square" array with rotated one.
46
47
    while [ "$column" -lt "$Columns" ]
48
49
50
     let "index = $row * $Rows + $column"
      echo -n "${alpha[index]} " # alpha[$row][$column]
 51
      let "column += 1"
52
53
    done
54
55 let "row += 1"
56 echo
57
58 done
59
60 # The simpler equivalent is
61 # echo ${alpha[*]} | xargs -n $Columns
63 echo
64 }
6.5
66 filter ()
               # Filter out negative array indices.

127
128 exit 0
129
130 # This is a rather contrived, not to mention inelegant simulation.
131
132 # Exercises:
133 # -----
134 # 1) Rewrite the array loading and printing functions
         in a more intuitive and less kludgy fashion.
136 #
137 # 2) Figure out how the array rotation functions work.
138 #
         Hint: think about the implications of backwards-indexing an array.
139 #
140 # 3) Rewrite this script to handle a non-square array,
141 #
         such as a 6 X 4 one.
142 #
         Try to minimize "distortion" when the array is rotated.
```

A two-dimensional array is essentially equivalent to a one-dimensional one, but with additional addressing modes for referencing and manipulating the individual elements by row and column position.

For an even more elaborate example of simulating a two-dimensional array, see Example A-10.

For more interesting scripts using arrays, see:

- Example 11-3
- Example A-24
- Example A-40

Prev **Home** Next <u>Up</u> List Constructs /dev and /proc Advanced Bash-Scripting Guide: An in-depth exploration of the art of shell scripting

<u>Prev</u> <u>Next</u>

Chapter 27. /dev and /proc

A Linux or UNIX machine typically has the /dev and /proc special-purpose directories.

27.1. /dev

The /dev directory contains entries for the physical *devices* that may or may not be present in the hardware.

[1] The hard drive partitions containing the mounted filesystem(s) have entries in /dev, as a simple <u>df</u> shows.

```
bash$ df
Filesystem 1k-blocks Used Available Use%
Mounted on
/dev/hda6 495876 222748 247527 48% /
/dev/hda1 50755 3887 44248 9% /boot
/dev/hda8 367013 13262 334803 4% /home
/dev/hda5 1714416 1123624 503704 70% /usr
```

Among other things, the /dev directory also contains *loopback* devices, such as /dev/loop0. A loopback device is a gimmick that allows an ordinary file to be accessed as if it were a block device. [2] This enables mounting an entire filesystem within a single large file. See Example 16-8 and Example 16-7.

For instance:

To mount a USB flash drive, append the following line to /etc/fstab. [3]

```
1 /dev/sdal /mnt/flashdrive auto noauto, user, noatime 0 0 (See also Example A-25.)
```

Checking whether a disk is in the CD-burner (soft-linked to /dev/hdc):

```
1 head -1 /dev/hdc
 4 # head: cannot open '/dev/hdc' for reading: No medium found
 5 #
     (No disc in the drive.)
 6
 7 # head: error reading '/dev/hdc': Input/output error
 8 # (There is a disk in the drive, but it can't be read;
 9 #+ possibly it's an unrecorded CDR blank.)
1.0
11 # Stream of characters and assorted gibberish
12 # (There is a pre-recorded disk in the drive,
13 #+ and this is raw output -- a stream of ASCII and binary data.)
14 # Here we see the wisdom of using 'head' to limit the output
15 #+ to manageable proportions, rather than 'cat' or something similar.
16
17
18 # Now, it's just a matter of checking/parsing the output and taking
19 #+ appropriate action.
```

When executing a command on a /dev/tcp/\$host/\$port pseudo-device file, Bash opens a TCP connection to the associated *socket*.

A *socket* is a communications node associated with a specific I/O port. (This is analogous to a *hardware socket*, or *receptacle*, for a connecting cable.) It permits data transfer between hardware devices on the same machine, between machines on the same network, between machines across different networks, and, of course, between machines at different locations on the Internet.

Getting the time from nist.gov:

```
bash$ cat </dev/tcp/time.nist.gov/13
53082 04-03-18 04:26:54 68 0 0 502.3 UTC(NIST) *
```

[Mark contributed the above example.]

Downloading a URL:

```
bash$ exec 5<>/dev/tcp/www.net.cn/80
bash$ echo -e "GET / HTTP/1.0\n" >&5
bash$ cat <&5</pre>
```

[Thanks, Mark and Mihai Maties.]

Example 27-1. Using /dev/tcp for troubleshooting

```
1 #!/bin/bash
2 # dev-tcp.sh: /dev/tcp redirection to check Internet connection.
4 # Script by Troy Engel.
5 # Used with permission.
7 TCP_HOST=www.dns-diy.com
                             # A known spam-friendly ISP.
8 TCP_PORT=80
                              # Port 80 is http.
10 # Try to connect. (Somewhat similar to a 'ping' . . .)
11 echo "HEAD / HTTP/1.0" >/dev/tcp/${TCP_HOST}/${TCP_PORT}
12 MYEXIT=$?
13
14 : <<EXPLANATION
15 If bash was compiled with --enable-net-redirections, it has the capability of
16 using a special character device for both TCP and UDP redirections. These
17 redirections are used identically as STDIN/STDOUT/STDERR. The device entries
18 are 30,36 for /dev/tcp:
19
20
   mknod /dev/tcp c 30 36
2.1
22 >From the bash reference:
23 /dev/tcp/host/port
      If host is a valid hostname or Internet address, and port is an integer
25 port number or service name, Bash attempts to open a TCP connection to the
26 corresponding socket.
27 EXPLANATION
2.8
29
30 if [ "X$MYEXIT" = "X0" ]; then
31 echo "Connection successful. Exit code: $MYEXIT"
33
   echo "Connection unsuccessful. Exit code: $MYEXIT"
34 fi
36 exit $MYEXIT
```

Notes

[1] The entries in /dev provide mount points for physical and virtual devices. These entries use very little drive space.

- Some devices, such as /dev/null, /dev/zero, and /dev/urandom are virtual. They are not actual physical devices and exist only in software.
- [2] A *block device* reads and/or writes data in chunks, or blocks, in contrast to a *character device*, which acesses data in character units. Examples of block devices are a hard drive and CD ROM drive. An example of a character device is a keyboard.
- [3] Of course, the mount point /mnt/flashdrive must exist. If not, then, as *root*, **mkdir** /mnt/flashdrive.

To actually mount the drive, use the following command: **mount /mnt/flashdrive**

Newer Linux distros automount flash drives in the /media directory.

3 if [ "$CPU" = "Pentium(R)" ]
4 then
5    run_some_commands
6    ...
7 else
8    run_different_commands
9    ...
10 fi
11
12
13
14 cpu_speed=$( fgrep "cpu MHz" /proc/cpuinfo | awk '{print $4}' )
15 # Current operating speed (in MHz) of the cpu on your machine.
16 # On a laptop this may vary, depending on use of battery
17 #+ or AC power.</pre>
```

```
1 #!/bin/bash
 2 # get-commandline.sh
 3 # Get the command-line parameters of a process.
5 OPTION=cmdline
7 # Identify PID.
8 pid=$( echo $(pidof "$1") | awk '{ print $1 }' )
                              ^^^^^^^^^^^ of multiple instances.
9 # Get only first
10
11 echo
12 echo "Process ID of (first instance of) "$1" = $pid"
13 echo -n "Command-line arguments: "
14 cat /proc/"$pid"/"$OPTION" | xargs -0 echo
                            ^^^^^
15 # Formats output:
16 # (Thanks, Han Holl, for the fixup!)
```

```
17
18 echo; echo
19
20
21 # For example:
22 # sh get-commandline.sh xterm
```

It is even possible to control certain peripherals with commands sent to the /proc directory.

```
root# echo on > /proc/acpi/ibm/light
```

This turns on the *Thinklight* in certain models of IBM/Lenovo Thinkpads.

Of course, caution is advised when writing to /proc.

The /proc directory contains subdirectories with unusual numerical names. Every one of these names maps to the <u>process ID</u> of a currently running process. Within each of these subdirectories, there are a number of files that hold useful information about the corresponding process. The stat and status files keep running statistics on the process, the cmdline file holds the command-line arguments the process was invoked with, and the exe file is a symbolic link to the complete path name of the invoking process. There are a few more such files, but these seem to be the most interesting from a scripting standpoint.

Example 27-2. Finding the process associated with a PID

```
1 #!/bin/bash
 2 # pid-identifier.sh:
 3 # Gives complete path name to process associated with pid.
 5 ARGNO=1 # Number of arguments the script expects.
 6 E WRONGARGS=65
 7 E_BADPID=66
 8 E_NOSUCHPROCESS=67
9 E_NOPERMISSION=68
10 PROCFILE=exe
11
12 if [ $# -ne $ARGNO ]
echo "Usage: `basename $0` PID-number" >&2 # Error message >stderr.
15 exit $E_WRONGARGS
16 fi
17
18 pidno=$( ps ax | grep $1 | awk '{ print $1 }' | grep $1 )
19 # Checks for pid in "ps" listing, field #1.
20 # Then makes sure it is the actual process, not the process invoked by this script.
21 # The last "grep $1" filters out this possibility.
```

```
22 #
23 #
     pidno=$( ps ax | awk '{ print $1 }' | grep $1 )
24 #
     also works, as Teemu Huovila, points out.
25
26 if [ -z "$pidno" ] # If, after all the filtering, the result is a zero-length string,
                      #+ no running process corresponds to the pid given.
28 echo "No such process running."
29 exit $E_NOSUCHPROCESS
30 fi
31
32 # Alternatively:
33 # if ! ps $1 > /dev/null 2>&1
     then
34 #
                          # no running process corresponds to the pid given.
       echo "No such process running."
35 #
36 #
        exit $E_NOSUCHPROCESS
37 #
       fi
38
39 # To simplify the entire process, use "pidof".
40
41
42 if [ ! -r "/proc/$1/$PROCFILE" ] # Check for read permission.
43 then
44 echo "Process $1 running, but..."
45 echo "Can't get read permission on /proc/$1/$PROCFILE."
46 exit $E_NOPERMISSION # Ordinary user can't access some files in /proc.
47 fi
48
49 # The last two tests may be replaced by:
50 # if ! kill -0 $1 > /dev/null 2>&1 # '0' is not a signal, but
51
                                        # this will test whether it is possible
52
                                        # to send a signal to the process.
53 #
     then echo "PID doesn't exist or you're not its owner" >&2
54 #
       exit $E_BADPID
55 #
      fi
56
57
59 exe_file=$( ls -1 /proc/$1 | grep "exe" | awk '{ print $11 }' )
60 # Or exe_file=$( ls -l /proc/$1/exe | awk '{print $11}')
61 #
62 # /proc/pid-number/exe is a symbolic link
63 #+ to the complete path name of the invoking process.
65 if [ -e "$exe_file" ] # If /proc/pid-number/exe exists,
66 then
                         #+ then the corresponding process exists.
67 echo "Process #$1 invoked by $exe_file."
68 else
69 echo "No such process running."
70 fi
71
72
73 # This elaborate script can *almost* be replaced by
74 # ps ax | grep $1 | awk '{ print $5 }'
75 # However, this will not work...
76 #+ because the fifth field of 'ps' is argv[0] of the process,
77 #+ not the executable file path.
78 #
79 # However, either of the following would work.
80 # find /proc/$1/exe -printf '%l\n'
          lsof -aFn -p $1 -d txt | sed -ne 's/^n//p'
81 #
83 # Additional commentary by Stephane Chazelas.
84
85 exit 0
```

Example 27-3. On-line connect status

```
1 #!/bin/bash
 3 PROCNAME=pppd
                   # ppp daemon
 4 PROCFILENAME=status # Where to look.
 5 NOTCONNECTED=65
 6 INTERVAL=2
                        # Update every 2 seconds.
 8 pidno=$( ps ax | grep -v "ps ax" | grep -v grep | grep $PROCNAME | awk '{ print $1 }')
 9 # Finding the process number of 'pppd', the 'ppp daemon'.
10 # Have to filter out the process lines generated by the search itself.
11 #
12 # However, as Oleg Philon points out,
13 #+ this could have been considerably simplified by using "pidof".
14 # pidno=$( pidof $PROCNAME )
15 #
16 # Moral of the story:
17 #+ When a command sequence gets too complex, look for a shortcut.
18
20 if [ -z "$pidno" ] # If no pid, then process is not running.
21 then
2.2.
   echo "Not connected."
   exit $NOTCONNECTED
23
24 else
25 echo "Connected."; echo
26 fi
28 while [ true ]
                      # Endless loop, script can be improved here.
29 do
30
    if [ ! -e "/proc/$pidno/$PROCFILENAME" ]
31
32
    # While process running, then "status" file exists.
    then
33
     echo "Disconnected."
34
      exit $NOTCONNECTED
35
36
    fi
37
38 netstat -s | grep "packets received" # Get some connect statistics.
39 netstat -s | grep "packets delivered"
40
41
42
   sleep $INTERVAL
43 echo; echo
44
45 done
46
47 exit 0
48
49 # As it stands, this script must be terminated with a Control-C.
50
51 #
       Exercises:
52. #
53 #
        Improve the script so it exits on a "q" keystroke.
54 #
       Make the script more user-friendly in other ways.
```

In general, it is dangerous to *write* to the files in /proc, as this can corrupt the filesystem or crash the machine.

Notes

Chapter 28. Of Zeros and Nulls

/dev/zero and /dev/null

Uses of /dev/null

Think of /dev/null as a "black hole." It is the nearest equivalent to a write-only file. Everything written to it disappears forever. Attempts to read or output from it result in nothing. Nevertheless, /dev/null can be quite useful from both the command line and in scripts.

Suppressing stdout.

```
1 cat $filename >/dev/null
2 # Contents of the file will not list to stdout.
```

Suppressing stderr (from Example 15-3).

```
1 rm $badname 2>/dev/null
2 # So error messages [stderr] deep-sixed.
```

Suppressing output from both stdout and stderr.

```
1 cat $filename 2>/dev/null >/dev/null
2 # If "$filename" does not exist, there will be no error message output.
3 # If "$filename" does exist, the contents of the file will not list to stdout.
4 # Therefore, no output at all will result from the above line of code.
5 #
6 # This can be useful in situations where the return code from a command
7 #+ needs to be tested, but no output is desired.
8 #
9 # cat $filename &>/dev/null
10 # also works, as Baris Cicek points out.
```

Deleting contents of a file, but preserving the file itself, with all attendant permissions (from <u>Example 2-1</u> and <u>Example 2-3</u>):

```
1 cat /dev/null > /var/log/messages
2 # : > /var/log/messages has same effect, but does not spawn a new process.
3
4 cat /dev/null > /var/log/wtmp
```

Automatically emptying the contents of a logfile (especially good for dealing with those nasty "cookies" sent by commercial Web sites):

Example 28-1. Hiding the cookie jar

```
1 if [ -f ~/.netscape/cookies ] # Remove, if exists.
2 then
3  rm -f ~/.netscape/cookies
4 fi
5
6 ln -s /dev/null ~/.netscape/cookies
7 # All cookies now get sent to a black hole, rather than saved to disk.
```

Uses of /dev/zero

Like /dev/null, /dev/zero is a pseudo-device file, but it actually produces a stream of nulls (binary zeros, not the ASCII kind). Output written to /dev/zero disappears, and it is fairly difficult to actually read the nulls from there, though it can be done with od or a hex editor. The chief use for /dev/zero is in creating an initialized dummy file of predetermined length intended as a temporary

Example 28-2. Setting up a swapfile using /dev/zero

```
1 #!/bin/bash
2 # Creating a swapfile.
3
                 # Root has $UID 0.
4 ROOT_UID=0
5 E_WRONG_USER=65 # Not root?
7 FILE=/swap
8 BLOCKSIZE=1024
9 MINBLOCKS=40
10 SUCCESS=0
11
12
13 # This script must be run as root.
14 if [ "$UID" -ne "$ROOT_UID" ]
15 then
16 echo; echo "You must be root to run this script."; echo
   exit $E_WRONG_USER
18 fi
19
20
21 blocks=${1:-$MINBLOCKS} # Set to default of 40 blocks,
22
                              #+ if nothing specified on command line.
23 # This is the equivalent of the command block below.
25 # if [ -n "$1" ]
26 # then
27 # blocks=$1
28 # else
29 # blocks=$MINBLOCKS
30 # fi
31 # ---
32
33
34 if [ "$blocks" -lt $MINBLOCKS ]
35 then
36 blocks=$MINBLOCKS # Must be at least 40 blocks long.
37 fi
38
39
41 echo "Creating swap file of size $blocks blocks (KB)."
42 dd if=/dev/zero of=$FILE bs=$BLOCKSIZE count=$blocks # Zero out file.
43 mkswap $FILE $blocks
                               # Designate it a swap file.
44 swapon $FILE
                               # Activate swap file.
45 # Note that if one or more of these commands fails,
46 #+ then it could cause nasty problems.
48
49 # Exercise:
50 # Rewrite the above block of code so that if it does not execute
51 #+ successfully, then:
52 # 1) an error message is echoed to stderr,
53 # 2) all temporary files are cleaned up, and
54 # 3) the script exits in an orderly fashion with an
55 #+
       appropriate error code.
56
57 echo "Swap file created and activated."
58
59 exit $SUCCESS
```

Another application of /dev/zero is to "zero out" a file of a designated size for a special purpose, such as mounting a filesystem on a <u>loopback device</u> (see <u>Example 16-8</u>) or "securely" deleting a file (see <u>Example 15-58</u>).

Example 28-3. Creating a ramdisk

```
1 #!/bin/bash
 2 # ramdisk.sh
 4 # A "ramdisk" is a segment of system RAM memory
 5 #+ which acts as if it were a filesystem.
 6 # Its advantage is very fast access (read/write time).
 7 # Disadvantages: volatility, loss of data on reboot or powerdown.
 8 #+
                  less RAM available to system.
9 #
10 # Of what use is a ramdisk?
11 # Keeping a large dataset, such as a table or dictionary on ramdisk,
12 #+ speeds up data lookup, since memory access is much faster than disk access.
13
14
15 E_NON_ROOT_USER=70
                               # Must run as root.
16 ROOTUSER_NAME=root
17
18 MOUNTPT=/mnt/ramdisk
19 SIZE=2000
                              # 2K blocks (change as appropriate)
20 BLOCKSIZE=1024
                               # 1K (1024 byte) block size
21 DEVICE=/dev/ram0
                               # First ram device
23 username=`id -nu`
24 if [ "$username" != "$ROOTUSER_NAME" ]
25 then
   echo "Must be root to run \"`basename $0`\"."
2.7
   exit $E_NON_ROOT_USER
28 fi
29
30 if [ ! -d "$MOUNTPT" ]  # Test whether mount point already there,
31 then  #+ so no error if this script is run
32 mkdir $MOUNTPT
                               #+ multiple times.
33 fi
34
36 dd if=/dev/zero of=$DEVICE count=$SIZE bs=$BLOCKSIZE # Zero out RAM device.
37
                                                     # Why is this necessary?
                               # Create an ext2 filesystem on it.
38 mke2fs $DEVICE
39 mount $DEVICE $MOUNTPT # Mount it.
40 chmod 777 $MOUNTPT
                               # Enables ordinary user to access ramdisk.
                           # However, must be root to unmount it.
41
43 # Need to test whether above commands succeed. Could cause problems otherwise.
44 # Exercise: modify this script to make it safer.
46 echo "\"$MOUNTPT\" now available for use."
47 # The ramdisk is now accessible for storing files, even by an ordinary user.
48
49 # Caution, the ramdisk is volatile, and its contents will disappear
50 #+ on reboot or power loss.
51 # Copy anything you want saved to a regular directory.
52
53 # After reboot, run this script to again set up ramdisk.
54 # Remounting /mnt/ramdisk without the other steps will not work.
55
56 # Suitably modified, this script can by invoked in /etc/rc.d/rc.local,
```

```
57 #+ to set up ramdisk automatically at bootup.
58 # That may be appropriate on, for example, a database server.
59
60 exit 0
```

In addition to all the above, $\mbox{\tt /dev/zero}$ is needed by ELF binaries.

<u>Prev</u>	<u>Home</u>	Next

	Advanced Bash-Scripting Guide: An in-depth exploration of the art of sh	ell scripting
<u>Prev</u>		<u>Next</u>

Chapter 29. Debugging

Debugging is twice as hard as writing the code in the first place. Therefore, if you write the code as cleverly as possible, you are, by definition, not smart enough to debug it.

--Brian Kernighan

The Bash shell contains no built-in debugger, and only bare-bones debugging-specific commands and constructs. Syntax errors or outright typos in the script generate cryptic error messages that are often of no help in debugging a non-functional script.

Example 29-1. A buggy script

```
1 #!/bin/bash
2 # ex74.sh
3
4 # This is a buggy script.
5 # Where, oh where is the error?
6
7 a=37
8
9 if [$a -gt 27 ]
10 then
11 echo $a
12 fi
13
14 exit 0
```

Output from script:

```
./ex74.sh: [37: command not found What's wrong with the above script? Hint: after the if.
```

Example 29-2. Missing keyword

```
1 #!/bin/bash
2 # missing-keyword.sh: What error message will this generate?
3
4 for a in 1 2 3
5 do
6 echo "$a"
7 # done # Required keyword 'done' commented out in line 7.
8
9 exit 0
```

Output from script:

```
missing-keyword.sh: line 10: syntax error: unexpected end of file
```

Note that the error message does *not* necessarily reference the line in which the error occurs, but the line where the Bash interpreter finally becomes aware of the error.

Error messages may disregard comment lines in a script when reporting the line number of a syntax error.

Example 29-3. test24: another buggy script

```
1 #!/bin/bash
2
3 # This script is supposed to delete all filenames in current directory
4 #+ containing embedded spaces.
5 # It doesn't work.
6 # Why not?
7
8
9 badname=`ls | grep ' '`
10
11 # Try this:
12 # echo "$badname"
13
14 rm "$badname"
15
16 exit 0
```

Try to find out what's wrong with <u>Example 29-3</u> by uncommenting the **echo** "**\$badname**" line. Echo statements are useful for seeing whether what you expect is actually what you get.

In this particular case, **rm** "**\$badname**" will not give the desired results because \$badname should not be quoted. Placing it in quotes ensures that **rm** has only one argument (it will match only one filename). A partial fix is to remove to quotes from \$badname and to reset \$IFS to contain only a newline, **IFS=\$'\n'**. However, there are simpler ways of going about it.

```
1 # Correct methods of deleting filenames containing spaces.
2 rm *\ *
3 rm *" "*
4 rm *' '*
5 # Thank you. S.C.
```

Summarizing the symptoms of a buggy script,

- 1. It bombs with a "syntax error" message, or
- 2. It runs, but does not work as expected (logic error).
- 3. It runs, works as expected, but has nasty side effects (logic bomb).

Tools for debugging non-working scripts include

- 1. <u>echo</u> statements at critical points in the script to trace the variables, and otherwise give a snapshot of what is going on.
 - (i) Even better is an **echo** that echoes only when *debug* is on.

```
11 Whatever=whatnot
12 debecho $Whatever  # whatnot
13
14 DEBUG=
15 Whatever=notwhat
16 debecho $Whatever  # (Will not echo.)
```

- 2. using the <u>tee</u> filter to check processes or data flows at critical points.
- 3. setting option flags -n -v -x

sh -n scriptname checks for syntax errors without actually running the script. This is the equivalent of inserting set -n or set -o noexec into the script. Note that certain types of syntax errors can slip past this check.

sh -**v scriptname** echoes each command before executing it. This is the equivalent of inserting **set** -**v** or **set** -**o verbose** in the script.

The -n and -v flags work well together. **sh** -nv **scriptname** gives a verbose syntax check.

sh -x scriptname echoes the result each command, but in an abbreviated manner. This is the equivalent of inserting set -x or set -o xtrace in the script.

Inserting **set -u** or **set -o nounset** in the script runs it, but gives an unbound variable error message at each attempt to use an undeclared variable.

4. Using an "assert" function to test a variable or condition at critical points in a script. (This is an idea borrowed from C.)

Example 29-4. Testing a condition with an assert

```
1 #!/bin/bash
2 # assert.sh
5 assert () # If condition false,
6 {
                      #+ exit from script
7
                      #+ with appropriate error message.
8 E_PARAM_ERR=98
9 E_ASSERT_FAILED=99
10
11
12 if [ -z "$2" ]  # Not enough parameters passed
13 then  #+ to assert() function.
14 return $E_PARAM_ERR # No damage done.
15 fi
16
17
  lineno=$2
18
19 if [! $1]
20
   then
   echo "Assertion failed: \"$1\""
21
    echo "File \"$0\", line $lineno" # Give name of file and line number.
23
    exit $E_ASSERT_FAILED
2.4
   # else
25
   # return
   # and continue executing the script.
2.6
28 } # Insert a similar assert() function into a script you need to debug.
30
```

```
31
32 a=5
33 b=4
34 condition="$a -lt $b" # Error message and exit from script.
                             # Try setting "condition" to something else
                             #+ and see what happens.
36
37
38 assert "$condition" $LINENO
39 # The remainder of the script executes only if the "assert" does not fail.
40
41
42 # Some commands.
43 # Some more commands . .
44 echo "This statement echoes only if the \"assert\" does not fail."
45 # . . .
46 # More commands . . .
47
48 exit $?
```

- 5. Using the <u>\$LINENO</u> variable and the <u>caller</u> builtin.
- tranning at avit

trapping at exit.

The **exit** command in a script triggers a signal 0, terminating the process, that is, the script itself. [1] It is often useful to trap the **exit**, forcing a "printout" of variables, for example. The **trap** must be the first command in the script.

Trapping signals

trap

Specifies an action on receipt of a signal; also useful for debugging.

A *signal* is simply a message sent to a process, either by the kernel or another process, telling it to take some specified action (usually to terminate). For example, hitting a **Control-C**, sends a user interrupt, an INT signal, to a running program.

```
1 trap '' 2
2 # Ignore interrupt 2 (Control-C), with no action specified.
3
4 trap 'echo "Control-C disabled."' 2
5 # Message when Control-C pressed.
```

Example 29-5. Trapping at exit

```
1 #!/bin/bash
2 # Hunting variables with a trap.
3
4 trap 'echo Variable Listing --- a = $a b = $b' EXIT
5 # EXIT is the name of the signal generated upon exit from a script.
6 #
7 # The command specified by the "trap" doesn't execute until
8 #+ the appropriate signal is sent.
9
10 echo "This prints before the \"trap\" --"
11 echo "even though the script sees the \"trap\" first."
12 echo
13
14 a=39
15
16 b=36
```

```
17
18 exit 0
19 # Note that commenting out the 'exit' command makes no difference,
20 #+ since the script exits in any case after running out of commands.
```

Example 29-6. Cleaning up after Control-C

```
1 #!/bin/bash
 2 # logon.sh: A quick 'n dirty script to check whether you are on-line yet.
 4 umask 177 # Make sure temp files are not world readable.
7 TRUE=1
 8 LOGFILE=/var/log/messages
9 # Note that $LOGFILE must be readable
10 #+ (as root, chmod 644 /var/log/messages).
11 TEMPFILE=temp.$$
12 # Create a "unique" temp file name, using process id of the script.
        Using 'mktemp' is an alternative.
13 #
14 #
        For example:
        TEMPFILE=`mktemp temp.XXXXXX`
16 KEYWORD=address
17 # At logon, the line "remote IP address xxx.xxx.xxx"
18 #
                         appended to /var/log/messages.
19 ONLINE=22
20 USER INTERRUPT=13
21 CHECK_LINES=100
22 # How many lines in log file to check.
24 trap 'rm -f $TEMPFILE; exit $USER_INTERRUPT' TERM INT
25 # Cleans up the temp file if script interrupted by control-c.
26
27 echo
2.8
29 while [ $TRUE ] #Endless loop.
30 do
31 tail -n $CHECK_LINES $LOGFILE> $TEMPFILE
32 # Saves last 100 lines of system log file as temp file.
   # Necessary, since newer kernels generate many log messages at log on.
33
   search=`grep $KEYWORD $TEMPFILE`
34
     # Checks for presence of the "IP address" phrase,
35
36
    #+ indicating a successful logon.
37
38
    if [ ! -z "$search" ] # Quotes necessary because of possible spaces.
39
    then
     echo "On-line"
40
41
      rm -f $TEMPFILE # Clean up temp file.
      exit $ONLINE
42
   else
4.3
    echo -n "."
44
                          # The -n option to echo suppresses newline,
45
                          #+ so you get continuous rows of dots.
   fi
46
47
48 sleep 1
49 done
50
51
52 # Note: if you change the KEYWORD variable to "Exit",
53 #+ this script can be used while on-line
54 #+ to check for an unexpected logoff.
55
```

```
56 # Exercise: Change the script, per the above note,
57 # and prettify it.
58
59 exit 0
60
61
62 # Nick Drage suggests an alternate method:
64 while true
65 do ifconfig ppp0 | grep UP 1> /dev/null && echo "connected" && exit 0
66 echo -n "." # Prints dots (....) until connected.
67 sleep 2
68 done
69
70 # Problem: Hitting Control-C to terminate this process may be insufficient.
             (Dots may keep on echoing.)
72 # Exercise: Fix this.
74
75
76 # Stephane Chazelas has yet another alternative:
77
78 CHECK_INTERVAL=1
79
80 while ! tail -n 1 "$LOGFILE" | grep -q "$KEYWORD"
81 do echo -n .
82 sleep $CHECK_INTERVAL
83 done
84 echo "On-line"
86 # Exercise: Discuss the relative strengths and weaknesses
              of each of these various approaches.
```

(Fig. 1) The DEBUG argument to **trap** causes a specified action to execute after every command in a script. This permits tracing variables, for example.

Example 29-7. Tracing a variable

```
1 #!/bin/bash
 3 trap 'echo "VARIABLE-TRACE> \$variable = \"$variable\""' DEBUG
 4 # Echoes the value of $variable after every command.
 6 variable=29
 8 echo "Just initialized \"\$variable\" to $variable."
10 let "variable *= 3"
11 echo "Just multiplied \"\$variable\" by 3."
12
13 exit $?
14
15 # The "trap 'command1 . . . command2 . . . 'DEBUG" construct is
16 #+ more appropriate in the context of a complex script,
17 #+ where placing multiple "echo $variable" statements might be
18 #+ clumsy and time-consuming.
19
20 # Thanks, Stephane Chazelas for the pointer.
21
22
23 Output of script:
25 VARIABLE-TRACE> $variable = ""
```

```
26 VARIABLE-TRACE> $variable = "29"
27 Just initialized "$variable" to 29.
28 VARIABLE-TRACE> $variable = "29"
29 VARIABLE-TRACE> $variable = "87"
30 Just multiplied "$variable" by 3.
31 VARIABLE-TRACE> $variable = "87"
```

Of course, the **trap** command has other uses aside from debugging.

Example 29-8. Running multiple processes (on an SMP box)

```
1 #!/bin/bash
2 # parent.sh
 3 # Running multiple processes on an SMP box.
 4 # Author: Tedman Eng
 6 # This is the first of two scripts,
 7 #+ both of which must be present in the current working directory.
9
10
11
12 LIMIT=$1  # Total number of process to start
13 NUMPROC=4  # Number of concurrent threads (forks?)
14 PROCID=1  # Starting Process ID
15 echo "My PID is $$"
16
17 function start_thread() {
if [ $PROCID -le $LIMIT ] ; then
19
                  ./child.sh $PROCID&
                  let "PROCID++"
20
21
          else
           echo "Limit reached."
23
             wait
24
             exit
25
          fi
26 }
27
28 while [ "$NUMPROC" -gt 0 ]; do
         start_thread;
29
          let "NUMPROC--"
30
31 done
32
33
34 while true
35 do
37 trap "start_thread" SIGRTMIN
38
39 done
40
41 exit 0
42
43
44
45 # ====== Second script follows ======
47
48 #!/bin/bash
49 # child.sh
50 # Running multiple processes on an SMP box.
51 # This script is called by parent.sh.
52 # Author: Tedman Eng
```

149
150 : <<SCRIPT_AUTHOR_COMMENTS
151 I had the need to run a program, with specified options, on a number of
152 different files, using a SMP machine. So I thought [I'd] keep running
153 a specified number of processes and start a new one each time . . . one
154 of these terminates.
155
156 The "wait" instruction does not help, since it waits for a given process
157 or *all* process started in background. So I wrote [this] bash script
158 that can do the job, using the "trap" instruction.
159 -- Vernia Damiano
160 SCRIPT_AUTHOR_COMMENTS
```

SIGNAL (two adjacent apostrophes) disables SIGNAL for the remainder of the script. **trap SIGNAL** restores the functioning of SIGNAL once more. This is useful to protect a critical portion of a script from an undesirable interrupt.

```
trap '' 2 # Signal 2 is Control-C, now disabled.
command
command
trap 2 # Reenables Control-C
```

<u>Version 3</u> of Bash adds the following special variables for use by the debugger.

- 1. \$BASH_ARGC
- 2. \$BASH_ARGV
- 3. \$BASH_COMMAND
- 4. \$BASH_EXECUTION_STRING
- 5. \$BASH_LINENO

6. \$BASH_SOURCE

7. \$BASH SUBSHELL

Notes

[1] By convention, signal 0 is assigned to exit.

Chapter 30. Options

Options are settings that change shell and/or script behavior.

The <u>set</u> command enables options within a script. At the point in the script where you want the options to take effect, use **set -o option-name** or, in short form, **set -option-abbrev**. These two forms are equivalent.

```
#!/bin/bash

set -o verbose

Echoes all commands before executing.

### Echoes all commands before executing.
```

```
1 #!/bin/bash
2
3 set -v
4 # Exact same effect as above.
5
```

To disable an option within a script, use set +o option-name or set +option-abbrev.

```
#!/bin/bash
 2
        set -o verbose
        # Command echoing on.
 5
        command
 6
        . . .
 7
        command
 8
      set +o verbose
 9
10
      # Command echoing off.
      command
11
       # Not echoed.
12
13
14
15
      set -v
16
      # Command echoing on.
17
       command
      command
20
      set +v
# Command echoing off.
21
22
23
      command
24
25
       exit 0
```

An alternate method of enabling options in a script is to specify them immediately following the #! script header.

```
1 #!/bin/bash -x
2 #
3 # Body of script follows.
4
```

It is also possible to enable script options from the command line. Some options that will not work with **set** are available this way. Among these are -i, force script to run interactive.

bash -o verbose script-name

The following is a listing of some useful options. They may be specified in either abbreviated form (preceded by a single dash) or by complete name (preceded by a *double* dash or by $-\circ$).

Table 30-1. Bash options

Abbreviation	Name	Effect	
-C	noclobber	Prevent overwriting of files by redirection (may be overridden by >I)	
-D	(none)	List double-quoted strings prefixed by \$, but do not execute commands in script	
-a	allexport	Export all defined variables	
-b	notify	Notify when jobs running in background terminate (not of much use in a script)	
-c	(none)	Read commands from	
-е	errexit	Abort script at first error, when a command exits with non-zero status (except in <u>until</u> or <u>while loops</u> , <u>if-tests</u> , <u>list constructs</u>)	
-f	noglob	Filename expansion (globbing) disabled	
-i	interactive	Script runs in interactive mode	
-n	noexec	Read commands in script, but do not execute them (syntax check)	
-o Option-Name	(none)	Invoke the Option-Name option	
-o posix	POSIX	Change the behavior of Bash, or invoked script, to conform to <u>POSIX</u> standard.	
-o pipefail	pipe failure	Causes a pipeline to return the <u>exit status</u> of the last command in the pipe that returned a non-zero return value.	
-p	privileged	Script runs as "suid" (caution!)	
-r	restricted	Script runs in <i>restricted</i> mode (see <u>Chapter 21</u>).	
-s	stdin	Read commands from stdin	
-t	(none)	Exit after first command	
-u	nounset	Attempt to use undefined variable outputs error message, and forces an exit	
-A	verbose	Print each command to stdout before executing it	
-x	xtrace	Similar to -v, but expands commands	
_	(none)	End of options flag. All other arguments are <u>positional parameters</u> .	
	(none)	Unset positional parameters. If arguments given (arg1 arg2), positional parameters set to arguments.

Advanced Bash-Scripting Guide: An in-depth exploration of the art of shell scripting

<u>Prev</u> <u>Next</u>

Chapter 31. Gotchas

Turandot: Gli enigmi sono tre, la morte una!

Caleph: No, no! Gli enigmi sono tre, una la vita!

Puccini

Here are some (non-recommended!) scripting practices that will bring excitement to an otherwise dull life.

Assigning reserved words or characters to variable names.

```
1 case=value0  # Causes problems.
2 23skidoo=value1  # Also problems.
3 # Variable names starting with a digit are reserved by the shell.
4 # Try _23skidoo=value1. Starting variables with an underscore is o.k.
5
6 # However . . . using just the underscore will not work.
7 _=25
8 echo $_  # $_ is a special variable set to last arg of last command.
9
10 xyz((!*=value2  # Causes severe problems.
11 # As of version 3 of Bash, periods are not allowed within variable names.
```

• Using a hyphen or other reserved characters in a variable name (or function name).

```
1 var-1=23
2 # Use 'var_1' instead.
3
4 function-whatever () # Error
5 # Use 'function_whatever ()' instead.
6
7
8 # As of version 3 of Bash, periods are not allowed within function names.
9 function.whatever () # Error
10 # Use 'functionWhatever ()' instead.
```

• Using the same name for a variable and a function. This can make a script difficult to understand.

```
1 do_something ()
2 {
3    echo "This function does something with \"$1\"."
4 }
5
6 do_something=do_something
7
8 do_something do_something
9
10 # All this is legal, but highly confusing.
```

• Using <u>whitespace</u> inappropriately. In contrast to other programming languages, Bash can be quite finicky about whitespace.

```
1 var1 = 23  # 'var1=23' is correct.
2 # On line above, Bash attempts to execute command "var1"
3 # with the arguments "=" and "23".
4
5 let c = $a - $b  # 'let c=$a-$b' or 'let "c = $a - $b"' are correct.
6
7 if [ $a -le 5]  # if [ $a -le 5 ] is correct.
8 # if [ "$a" -le 5 ] is even better.
9 # [[ $a -le 5 ]] also works.
```

• Not terminating with a <u>semicolon</u> the final command in a <u>code block within curly brackets</u>.

Assuming uninitialized variables (variables before a value is assigned to them) are "zeroed out". An uninitialized variable has a value of *null*, *not* zero.

```
1 #!/bin/bash
2
3 echo "uninitialized_var = $uninitialized_var"
4 # uninitialized_var =
```

Mixing up = and -eq in a test. Remember, = is for comparing literal variables and -eq for integers.

```
1 if [ "$a" = 273 ]  # Is $a an integer or string?
 2 if [ "$a" -eq 273 ] # If $a is an integer.
 4 # Sometimes you can interchange -eq and = without adverse consequences.
 5 # However . . .
 7
 8 a=273.0 \# Not an integer.
10 if [ "$a" = 273 ]
11 then
12 echo "Comparison works."
13 else
14 echo "Comparison does not work."
15 fi # Comparison does not work.
17 # Same with a="273" and a="0273".
18
19
20 # Likewise, problems trying to use "-eq" with non-integer values.
2.1
22 if [ "$a" -eq 273.0 ]
23 then
24 echo "a = $a"
25 fi # Aborts with an error message.
26 # test.sh: [: 273.0: integer expression expected
```

Misusing <u>string comparison</u> operators.

Example 31-1. Numerical and string comparison are not equivalent

```
1 #!/bin/bash
2 # bad-op.sh: Trying to use a string comparison on integers.
3
4 echo
5 number=1
6
7 # The following "while loop" has two errors:
8 #+ one blatant, and the other subtle.
9
10 while [ "$number" < 5 ] # Wrong! Should be: while [ "$number" -lt 5 ]
11 do
12 echo -n "$number"</pre>
```

```
13 let "number += 1"
14 done
15 # Attempt to run this bombs with the error message:
16 #+ bad-op.sh: line 10: 5: No such file or directory
17 # Within single brackets, "<" must be escaped,
18 #+ and even then, it's still wrong for comparing integers.
19
20
21 echo "-----"
2.2.
23
24 while [ "$number" \< 5 ] # 1 2 3 4
2.5 do
26 echo -n "$number"  # This *seems to work, but . . .
27 let "number += 1"  #+ it actually does an ASCII comparison,
                               #+ rather than a numerical one.
28 done
2.9
30 echo; echo "-----"
32 # This can cause problems. For example:
33
34 lesser=5
35 greater=105
36
37 if [ "$greater" \< "$lesser" ]</pre>
39 echo "$greater is less than $lesser"
                            # 105 is less than 5
41 # In fact, "105" actually is less than "5"
42 #+ in a string comparison (ASCII sort order).
43
44 echo
45
46 exit 0
```

Sometimes variables within "test" brackets ([]) need to be quoted (double quotes). Failure to do so may cause unexpected behavior. See Example 19-5, and Example 9-6.

Commands issued from a script may fail to execute because the script owner lacks execute permission for them. If a user cannot invoke a command from the command line, then putting it into a script will likewise fail. Try changing the attributes of the command in question, perhaps even setting the suid bit (as *root*, of course).

Attempting to use - as a redirection operator (which it is not) will usually result in an unpleasant surprise.

```
1 command1 2> - | command2
2 # Trying to redirect error output of command1 into a pipe . . .
3 # . . . will not work.
4
5 command1 2>& - | command2 # Also futile.
6
7 Thanks, S.C.
```

Using Bash <u>version 2+</u> functionality may cause a bailout with error messages. Older Linux machines may have version 1.XX of Bash as the default installation.

```
1 #!/bin/bash
2
3 minimum_version=2
4 # Since Chet Ramey is constantly adding features to Bash,
```

```
5 # you may set $minimum_version to 2.XX, 3.XX, or whatever is appropriate.
6 E_BAD_VERSION=80
7
8 if [ "$BASH_VERSION" \< "$minimum_version" ]
9 then
10 echo "This script works only with Bash, version $minimum or greater."
11 echo "Upgrade strongly recommended."
12 exit $E_BAD_VERSION
13 fi
14
15 ...</pre>
```

- Using Bash-specific functionality in a Bourne shell script (#!/bin/sh) on a non-Linux machine may cause unexpected behavior. A Linux system usually aliases sh to bash, but this does not necessarily hold true for a generic UNIX machine.
- Using undocumented features in Bash turns out to be a dangerous practice. In previous releases of this book there were several scripts that depended on the "feature" that, although the maximum value of an <u>exit</u> or <u>return</u> value was 255, that limit did not apply to *negative* integers. Unfortunately, in version 2.05b and later, that loophole disappeared. See <u>Example 23-9</u>.
- A script with DOS-type newlines ($\r \n$) will fail to execute, since #!/bin/bash\r\n is not recognized, not the same as the expected #!/bin/bash\n. The fix is to convert the script to UNIX-style newlines.

```
1 #!/bin/bash
2
3 echo "Here"
4
5 unix2dos $0  # Script changes itself to DOS format.
6 chmod 755 $0  # Change back to execute permission.
7  # The 'unix2dos' command removes execute permission.
8
9 ./$0  # Script tries to run itself again.
10  # But it won't work as a DOS file.
11
12 echo "There"
13
14 exit 0
```

A shell script headed by #!/bin/sh will not run in full Bash-compatibility mode. Some Bash-specific functions might be disabled. Scripts that need complete access to all the Bash-specific extensions should start with #!/bin/bash.

• <u>Putting whitespace in front of the terminating limit string</u> of a <u>here document</u> will cause unexpected behavior in a script.

A script may not **export** variables back to its <u>parent process</u>, the shell, or to the environment. Just as we learned in biology, a child process can inherit from a parent, but not vice versa.

```
1 WHATEVER=/home/bozo
2 export WHATEVER
3 exit 0
bash$ echo $WHATEVER
bash$
```

Sure enough, back at the command prompt, \$WHATEVER remains unset.

Setting and manipulating variables in a <u>subshell</u>, then attempting to use those same variables outside the scope of the subshell will result an unpleasant surprise.

Example 31-2. Subshell Pitfalls

```
1 #!/bin/bash
 2 # Pitfalls of variables in a subshell.
4 outer_variable=outer
5 echo
 6 echo "outer_variable = $outer_variable"
7 echo
9 (
10 # Begin subshell
12 echo "outer_variable inside subshell = $outer_variable"
13 inner_variable=inner # Set
14 echo "inner_variable inside subshell = $inner_variable"
15 outer_variable=inner # Will value change globally?
16 echo "outer_variable inside subshell = $outer_variable"
18 # Will 'exporting' make a difference?
19 # export inner_variable
20 # export outer_variable
21 # Try it and see.
23 # End subshell
24)
2.5
27 echo "inner_variable outside subshell = $inner_variable" # Unset.
28 echo "outer_variable outside subshell = $outer_variable" # Unchanged.
29 echo
30
31 exit 0
32
33 # What happens if you uncomment lines 19 and 20?
34 # Does it make a difference?
```

<u>Piping</u> **echo** output to a <u>read</u> may produce unexpected results. In this scenario, the **read** acts as if it were running in a subshell. Instead, use the <u>set</u> command (as in <u>Example 14-18</u>).

Example 31-3. Piping the output of *echo* to a *read*

```
1 #!/bin/bash
 2 # badread.sh:
 3 # Attempting to use 'echo and 'read'
 4 #+ to assign variables non-interactively.
 6 a=aaa
7 b=bbb
8 c=ccc
10 echo "one two three" | read a b c
11 # Try to reassign a, b, and c.
12
13 echo
14 echo "a = $a" # a = aaa
15 echo "b = $b" # b = bbb
16 echo "c = $c" # c = ccc
17 # Reassignment failed.
18
```

```
2.0
21 # Try the following alternative.
23 var='echo "one two three"'
24 set -- $var
25 a=$1; b=$2; c=$3
26
27 echo "----"
28 echo "a = $a" # a = one
29 echo "b = $b" # b = two
30 echo "c = $c" # c = three
31 # Reassignment succeeded.
32
33 # ----
35 # Note also that an echo to a 'read' works within a subshell.
36 # However, the value of the variable changes *only* within the subshell.
38 a=aaa
                # Starting all over again.
39 b=bbb
40 c=ccc
41
42 echo; echo
43 echo "one two three" | ( read a b c;
44 echo "Inside subshell: "; echo "a = a"; echo "b = b"; echo "c = c")
45 \# a = one
46 \# b = two
47 \# c = three
48 echo "-----"
49 echo "Outside subshell: "
50 echo "a = $a" # a = aaa
51 echo "b = $b" # b = bbb
52 echo "c = $c" # c = ccc
53 echo
54
55 exit 0
```

In fact, as Anthony Richardson points out, piping to any loop can cause a similar problem.

```
1 # Loop piping troubles.
 2 # This example by Anthony Richardson,
 3 #+ with addendum by Wilbert Berendsen.
 6 foundone=false
 7 find $HOME -type f -atime +30 -size 100k |
8 while true
9 do
10 read f
11 echo "$f is over 100KB and has not been accessed in over 30 days"
12 echo "Consider moving the file to archives."
13 foundone=true
14 # -----
15 echo "Subshell level = $BASH_SUBSHELL"
16 # Subshell level = 1
17
   # Yes, we're inside a subshell.
18 # --
19 done
20
21 # foundone will always be false here since it is
22 #+ set to true inside a subshell
23 if [ $foundone = false ]
24 then
25 echo "No files need archiving."
```

```
26 fi
2.7
28 # =========Now, here is the correct way:=====
30 foundone=false
31 for f in $(find $HOME -type f -atime +30 -size 100k) # No pipe here.
32 do
33
    echo "$f is over 100KB and has not been accessed in over 30 days"
34
     echo "Consider moving the file to archives."
35 foundone=true
36 done
37
38 if [ $foundone = false ]
39 then
40 echo "No files need archiving."
41 fi
42
43 # =========And here is another alternative==========
44
45 # Places the part of the script that reads the variables
46 #+ within a code block, so they share the same subshell.
47 # Thank you, W.B.
48
49 find $HOME -type f -atime +30 -size 100k | {
50 foundone=false
51
      while read f
52
      do
        echo "$f is over 100KB and has not been accessed in over 30 days"
        echo "Consider moving the file to archives."
55
        foundone=true
56
      done
57
58
      if ! $foundone
59
       then
60
        echo "No files need archiving."
61
       fi
62 }
```

A related problem occurs when trying to write the stdout of a tail -f piped to grep.

```
1 tail -f /var/log/messages | grep "$ERROR_MSG" >> error.log
2 # The "error.log" file will not have anything written to it.
```

Using "suid" commands within scripts is risky, as it may compromise system security. [1]

Using shell scripts for CGI programming may be problematic. Shell script variables are not "typesafe", and this can cause undesirable behavior as far as CGI is concerned. Moreover, it is difficult to "cracker-proof" shell scripts.

• Bash does not handle the <u>double slash (//) string</u> correctly.

Bash scripts written for Linux or BSD systems may need fixups to run on a commercial UNIX (or Apple OSX) machine. Such scripts often employ the GNU set of commands and filters, which have greater functionality than their generic UNIX counterparts. This is particularly true of such text processing utilities as \underline{tr} .

Danger is near thee --

Beware, beware, beware, beware.

Many brave hearts are asleep in the deep.

So beware --

Beware.

A.J. Lamb and H.W. Petrie

Notes

III Set	ting the <u>suid</u> permission on the script itself has no effect in Linux and	most other UNIX flavors.

Advanced Bash-Scripting Guide: An in-depth exploration of the art of shell scripting				
<u>Prev</u>		<u>Next</u>		

Chapter 32. Scripting With Style

Get into the habit of writing shell scripts in a structured and systematic manner. Even "on-the-fly" and "written on the back of an envelope" scripts will benefit if you take a few minutes to plan and organize your thoughts before sitting down and coding.

Herewith are a few stylistic guidelines. This is not intended as an Official Shell Scripting Stylesheet.

32.1. Unofficial Shell Scripting Stylesheet

• Comment your code. This makes it easier for others to understand (and appreciate), and easier for you to maintain.

```
1 PASS="$PASS${MATRIX:$(($RANDOM%${#MATRIX})):1}"
2 # It made perfect sense when you wrote it last year,
3 #+ but now it's a complete mystery.
4 # (From Antek Sawicki's "pw.sh" script.)
```

Add descriptive headers to your scripts and functions.

```
1 #!/bin/bash
 3 #************
           xyz.sh
written by Bozo Bozeman
 4 #
 5 #
              July 05, 2001
 8 # Clean up project files.
11 E_BADDIR=65 # No such directory.
12 projectdir=/home/bozo/projects # Directory to clean up.
13
14 # -----
15 # cleanup_pfiles ()
16 # Removes all files in designated directory.
17 # Parameter: $target_directory
18 # Returns: 0 on success, $E_BADDIR if something went wrong. #
19 # -----
20 cleanup_pfiles ()
22 if [ ! -d "$1" ] # Test if target directory exists.
echo "$1 is not a directory."
25
     return $E_BADDIR
26 fi
2.7
28 rm -f "$1"/*
29 return 0 # Success.
30 }
31
32 cleanup_pfiles $projectdir
34 exit 0
```

Be sure to put the #!/bin/bash at the beginning of the first line of the script, preceding any comment headers.

• Avoid using "magic numbers," [1] that is, "hard-wired" literal constants. Use meaningful variable names instead. This makes the script easier to understand and permits making changes and updates without breaking the application.

```
1 if [ -f /var/log/messages ]
2 then
3 ...
4 fi
5 # A year later, you decide to change the script to check /var/log/syslog.
6 # It is now necessary to manually change the script, instance by instance,
7 # and hope nothing breaks.
8
9 # A better way:
10 LOGFILE=/var/log/messages # Only line that needs to be changed.
11 if [ -f "$LOGFILE" ]
```

```
12 then
13 ...
14 fi
```

• Choose descriptive names for variables and functions.

```
1 fl=`ls -al $dirname`
                                        # Cryptic.
 2 file_listing=`ls -al $dirname`
                                        # Better.
 4
 5 MAXVAL=10  # All caps used for a script constant.
 6 while [ "$index" -le "$MAXVAL" ]
7 ...
8
9
10 E_NOTFOUND=75
                                        # Uppercase for an errorcode,
11
                                       # +and name begins with "E_".
12 if [ ! -e "$filename" ]
14
   echo "File $filename not found."
15 exit $E_NOTFOUND
16 fi
17
1.8
19 MAIL_DIRECTORY=/var/spool/mail/bozo # Uppercase for an environmental variable.
20 export MAIL_DIRECTORY
21
22
23 GetAnswer ()
                                        # Mixed case works well for a function.
24 {
   prompt=$1
25
   echo -n $prompt
26
27 read answer
28 return $answer
29 }
30
31 GetAnswer "What is your favorite number? "
32 favorite_number=$?
33 echo $favorite_number
34
35
36 _uservariable=23
                                       # Permissible, but not recommended.
37 # It's better for user-defined variables not to start with an underscore.
38 # Leave that for system variables.
```

• Use <u>exit codes</u> in a systematic and meaningful way.

```
1 E_WRONG_ARGS=65
2 ...
3 ...
4 exit $E_WRONG_ARGS
```

See also Appendix D.

Ender suggests using the exit codes in /usr/include/sysexits.h in shell scripts, though these are primarily intended for C and C++ programming.

• Use standardized parameter flags for script invocation. *Ender* proposes the following set of flags.

```
1 -a
         All: Return all information (including hidden file info).
         Brief: Short version, usually for other scripts.
2 -b
3 -с
         Copy, concatenate, etc.
       Daily: Use information from the whole day, and not merely
4 -d
5
         information for a specific instance/user.
       Extended/Elaborate: (often does not include hidden file info).
6 -е
       Help: Verbose usage w/descs, aux info, discussion, help.
7 -h
8
        See also -V.
```

```
9 -1
           Log output of script.
        Manual: Launch man-page for b
Numbers: Numerical data only.
10 -m
           Manual: Launch man-page for base command.
11 -n
12 -r
         Recursive: All files in a directory (and/or all sub-dirs).
13 -s
         Setup & File Maintenance: Config files for this script.
14 -u
         Usage: List of invocation flags for the script.
15 -v
          Verbose: Human readable output, more or less formatted.
       Version / License / Copy(right|left) / Contribs (email too).
16 -V
```

See also <u>Section F.1</u>.

- Break complex scripts into simpler modules. Use functions where appropriate. See Example 34-4.
- Don't use a complex construct where a simpler one will do.

```
1 COMMAND
2 if [ $? -eq 0 ]
3 ...
4 # Redundant and non-intuitive.
5
6 if COMMAND
7 ...
8 # More concise (if perhaps not quite as legible).
```

... reading the UNIX source code to the Bourne shell (/bin/sh). I was shocked at how much simple algorithms could be made cryptic, and therefore useless, by a poor choice of code style. I asked myself, "Could someone be proud of this code?"

Landon Noll

Notes

[1] In this context, "magic numbers" have an entirely different meaning than the <u>magic numbers</u> used to designate file types.

Advanced Bash-Scripting Guide: An in-depth exploration of the art of shell scripting

<u>Prev</u> Next

Chapter 33. Miscellany

Nobody really knows what the Bourne shell's grammar is. Even examination of the source code is little help.

--Tom Duff

33.1. Interactive and non-interactive shells and scripts

An *interactive* shell reads commands from user input on a tty. Among other things, such a shell reads startup files on activation, displays a prompt, and enables job control by default. The user can *interact* with the shell.

A shell running a script is always a non-interactive shell. All the same, the script can still access its tty. It is even possible to emulate an interactive shell in a script.

```
1 #!/bin/bash
 2 MY_PROMPT='$ '
 3 while :
 4 do
   echo -n "$MY_PROMPT"
   read line
 6
 7
   eval "$line"
 8
   done
9
10 exit 0
11
12 # This example script, and much of the above explanation supplied by
13 # Stéphane Chazelas (thanks again).
```

Let us consider an *interactive* script to be one that requires input from the user, usually with <u>read</u> statements (see <u>Example 14-3</u>). "Real life" is actually a bit messier than that. For now, assume an interactive script is bound to a tty, a script that a user has invoked from the console or an *xterm*.

Init and startup scripts are necessarily non-interactive, since they must run without human intervention. Many administrative and system maintenance scripts are likewise non-interactive. Unvarying repetitive tasks cry out for automation by non-interactive scripts.

Non-interactive scripts can run in the background, but interactive ones hang, waiting for input that never comes. Handle that difficulty by having an **expect** script or embedded <u>here document</u> feed input to an interactive script running as a background job. In the simplest case, redirect a file to supply input to a **read** statement (**read variable <file**). These particular workarounds make possible general purpose scripts that run in either interactive or non-interactive modes.

If a script needs to test whether it is running in an interactive shell, it is simply a matter of finding whether the *prompt* variable, <u>\$PS1</u> is set. (If the user is being prompted for input, then the script needs to display a prompt.)

```
1 if [ -z $PS1 ] # no prompt?
2 then
3  # non-interactive
4  ...
5 else
6  # interactive
7  ...
8 fi
```

Alternatively, the script can test for the presence of option "i" in the \$\frac{\section}{2}\$ flag.

```
1 case $- in
2 *i*)  # interactive shell
3 ;;
4 *)  # non-interactive shell
5 ;;
6 # (Courtesy of "UNIX F.A.Q.," 1993)
```

Scripts may be forced to run in interactive mode with the -i option or with a #!/bin/bash -i header.

Be aware that this can cause erratic script behavior or show error messages even when no error is present.

PrevHomeNextScripting With StyleUpOperator PrecedenceAdvanced Bash-Scripting Guide: An in-depth exploration of the art of shell scriptingPrevChapter 33. MiscellanyNext

33.2. Operator Precedence

In a script, operations execute in order of *precedence*: the higher precedence operations execute *before* the lower precedence ones. [1]

Table 33-1. Operator Precedence

Operator	Meaning	Comments
		HIGHEST PRECEDENCE
var++ var	post-increment, post-decrement	<u>C-style</u> operators
++varvar	pre-increment, pre-decrement	
! ~	negation	logical / bitwise, inverts sense of following operator
**	<u>exponentiation</u>	arithmetic operation
* / %	multiplication, division, modulo	arithmetic operation
+ -	addition, subtraction	arithmetic operation
<< >>	left, right shift	<u>bitwise</u>
-z -n	unary comparison	string is/is-not <i>null</i>
-e -f -t -x, etc.	unary comparison	files
< -lt > -gt <= -le >= -ge	compound comparison	string and integer
-nt -ot -ef	compound comparison	files
== -eq != -ne	equality / inequality	test operators, string and integer
&	AND	bitwise
۸	XOR	exclusive OR, bitwise
I	OR	bitwise
&& -a	AND	logical, compound comparison
-0	OR	logical, compound comparison
?:	trinary operator	C-style
=	assignment	(do not confuse with equality <i>test</i>)
*= /= %= += -= <<= >> &= !=	= combination assignment	times-equal, divide-equal, mod-equal, etc.
<u>, </u>	<u>comma</u>	links a sequence of operations

In practice, all you really need to remember is the following:

- The "My Dear Aunt Sally" mantra (*multiply, divide, add, subtract*) for the familiar <u>arithmetic operations</u>.
- The *compound* logical operators, &&, II, -a, and -o have low precedence.
- The order of evaluation of equal-precedence operators is usually *left-to-right*.

Now, let's utilize our knowledge of operator precedence to analyze a couple of lines from the /etc/init.d/functions file, as found in the *Fedora Core* Linux distro.

```
1 while [ -n "$remaining" -a "$retry" -gt 0 ]; do
3 # This looks rather daunting at first glance.
 6 # Separate the conditions:
7 while [ -n "$remaining" -a "$retry" -gt 0 ]; do
           --condition 1-- ^{-} --condition 2-
10 # If variable "$remaining" is not zero length
11 #+
         AND (-a)
12 #+ variable "$retry" is greater-than zero
13 #+ then
14 #+ the [ expresion-within-condition-brackets ] returns success (0)
15 #+ and the while-loop executes an iteration.
17 # Evaluate "condition 1" and "condition 2" ***before***
18 #+ ANDing them. Why? Because the AND (-a) has a lower precedence
19 #+ than the -n and -gt operators,
20 #+ and therefore gets evaluated *last*.
2.1
24 if [ -f /etc/sysconfig/i18n -a -z "${NOLOCALE:-}" ]; then
2.5
26
27 # Again, separate the conditions:
28 if [ -f /etc/sysconfig/i18n -a -z "${NOLOCALE:-}" ] ; then
       --condition 1----- ^^ --condition 2--
31 # If file "/etc/sysconfig/i18n" exists
         AND (-a)
32 #+
33 \#+ variable $NOLOCALE is zero length
34 #+ then
35 #+ the [ test-expresion-within-condition-brackets ] returns success (0)
36 #+ and the commands following execute.
37 #
38 # As before, the AND (-a) gets evaluated *last*
39 #+ because it has the lowest precedence of the operators within
40 #+ the test brackets.
41 #
42 #
     Note:
43 # ${NOLOCALE:-} is a parameter expansion that seems redundant.
44 # But, if $NOLOCALE has not been declared, it gets set to *null*,
45 #+ in effect declaring it.
46 # This makes a difference in some contexts.
```

i To avoid confusion or error in a complex sequence of test operators, break up the sequence into bracketed sections.

```
1 if [ "$v1" -gt "$v2" -o "$v1" -lt "$v2" -a -e "$filename" ]
2 # Unclear what's going on here...
3
4 if [[ "$v1" -gt "$v2" ]] || [[ "$v1" -lt "$v2" ]] && [[ -e "$filename" ]]
5 # Much better -- the condition tests are grouped in logical sections.
```

Notes

[1] Precedence, in this context, has approximately the same meaning as priority

PrevHomeNextMiscellanyUpShell WrappersAdvanced Bash-Scripting Guide: An in-depth exploration of the art of shell scriptingPrevChapter 33. MiscellanyNext

33.3. Shell Wrappers

A "wrapper" is a shell script that embeds a system command or utility, that saves a set of parameters passed to that command. [1] Wrapping a script around a complex command line simplifies invoking it. This is expecially useful with <u>sed</u> and <u>awk</u>.

A sed or awk script would normally be invoked from the command line by a sed -e 'commands' or awk 'commands'. Embedding such a script in a Bash script permits calling it more simply, and makes it "reusable". This also enables combining the functionality of sed and awk, for example piping the output of a set of sed commands to awk. As a saved executable file, you can then repeatedly invoke it in its original form or modified, without the inconvenience of retyping it on the command line.

Example 33-1. shell wrapper

```
1 #!/bin/bash
 3 # This is a simple script that removes blank lines from a file.
 4 # No argument checking.
 6 # You might wish to add something like:
 8 # E NOARGS=65
 9 # if [ -z "$1" ]
10 # then
11 # echo "Usage: `basename $0` target-file"
12 # exit $E_NOARGS
13 # fi
14
15
16 # Same as
17 # sed -e '/^$/d' filename
18 # invoked from the command line.
20 sed -e /^$/d "$1"
21 # The '-e' means an "editing" command follows (optional here).
22 # '^' is the beginning of line, '$' is the end.
23 # This match lines with nothing between the beginning and the end,
24 #+ blank lines.
25 # The 'd' is the delete command.
27 # Quoting the command-line arg permits
28 #+ whitespace and special characters in the filename.
30 # Note that this script doesn't actually change the target file.
31 # If you need to do that, redirect its output.
33 exit 0
```

Example 33-2. A slightly more complex shell wrapper

```
1 #!/bin/bash
2
3 # "subst", a script that substitutes one pattern for
4 #+ another in a file,
5 #+ i.e., "subst Smith Jones letter.txt".
```

```
7 ARGS=3
            # Script requires 3 arguments.
8 E_BADARGS=65 # Wrong number of arguments passed to script.
10 if [ $# -ne "$ARGS" ]
11 # Test number of arguments to script (always a good idea).
13 echo "Usage: `basename $0` old-pattern new-pattern filename"
14 exit $E_BADARGS
15 fi
16
17 old_pattern=$1
18 new_pattern=$2
19
20 if [ -f "$3" ]
21 then
22 file_name=$3
23 else
24 echo "File \"$3\" does not exist."
25 exit $E_BADARGS
26 fi
27
28
29 # Here is where the heavy work gets done.
30
31 # -----
32 sed -e "s/$old_pattern/$new_pattern/g" $file_name
35 # 's' is, of course, the substitute command in sed,
36 #+ and /pattern/ invokes address matching.
37 # The "g", or global flag causes substitution for *every*
38 #+ occurence of $old_pattern on each line, not just the first.
39 # Read the literature on 'sed' for an in-depth explanation.
40
41 exit 0  # Successful invocation of the script returns 0.
```

Example 33-3. A generic shell wrapper that writes to a logfile

```
1 #!/bin/bash
2 # Generic shell wrapper that performs an operation
3 #+ and logs it.
 5 # Must set the following two variables.
 6 OPERATION=
      Can be a complex chain of commands, for example an awk script or a pipe . . .
9 LOGFILE=
10 #
            Command-line arguments, if any, for the operation.
11
12
13 OPTIONS="$@"
14
15
16 # Log it.
17 echo "`date` + `whoami` + $OPERATION "$@"" >> $LOGFILE
18 # Now, do it.
19 exec $OPERATION "$@"
21 # It's necessary to do the logging before the operation.
22 # Why?
```

Example 33-4. A shell wrapper around an awk script

```
1 #!/bin/bash
 2 # pr-ascii.sh: Prints a table of ASCII characters.
 4 START=33 # Range of printable ASCII characters (decimal).
 5 END=125
 7 echo " Decimal Hex Character"
10 for ((i=START; i<=END; i++))
11 do
12 echo $i | awk '{printf(" %3d %2x %c\n", $1, $1, $1)}'
13 # The Bash printf builtin will not work in this context:
14 # printf "%c" "$i"
15 done
16
17 exit 0
18
19
20 # Decimal Hex
                    Character
21 # -----
22 # 33
23 # 34
24 # 35
25 # 36
              21
                       !
                        ***
              22
              23
                        #
              24
                        $
26 #
27 #
      . . .
28 #
29 #
     122
               7a
30 #
     123
               7b
                         {
31 #
     124
               7с
                         32 # 125
               7d
33
34
35 # Redirect the output of this script to a file
36 #+ or pipe it to "more": sh pr-asc.sh | more
```

Example 33-5. A shell wrapper around another awk script

```
1 #!/bin/bash
2
3 # Adds up a specified column (of numbers) in the target file.
4
5 ARGS=2
6 E_WRONGARGS=65
7
8 if [ $# -ne "$ARGS" ] # Check for proper no. of command line args.
9 then
10 echo "Usage: `basename $0` filename column-number"
11 exit $E_WRONGARGS
12 fi
13
14 filename=$1
15 column_number=$2
16
17 # Passing shell variables to the awk part of the script is a bit tricky.
18 # One method is to strong-quote the Bash-script variable
```

```
19 #+ within the awk script.
20 # $'$BASH_SCRIPT_VAR'
21 #
22 # This is done in the embedded awk script below.
23 # See the awk documentation for more details.
25 # A multi-line awk script is invoked by: awk ' ..... '
26
27
28 # Begin awk script.
29 # -----
30 awk '
31
32 { total += $'"${column_number}"'
33 }
34 END {
35 print total
36 }
37
38 ' "$filename"
39 # -----
40 # End awk script.
41
42
43 # It may not be safe to pass shell variables to an embedded awk script,
44 #+ so Stephane Chazelas proposes the following alternative:
45 #
46 # awk -v column_number="$column_number" '
47 # { total += $column_number
48 #
49 # END {
50 #
      print total
51 # }' "$filename"
52 #
53
54
55 exit 0
```

For those scripts needing a single do-it-all tool, a Swiss army knife, there is *Perl*. Perl combines the capabilities of **sed** and **awk**, and throws in a large subset of *C*, to boot. It is modular and contains support for everything ranging from object-oriented programming up to and including the kitchen sink. Short Perl scripts lend themselves to embedding in shell scripts, and there may even be some substance to the claim that Perl can totally replace shell scripting (though the author of this document remains skeptical).

Example 33-6. Perl embedded in a Bash script

It is even possible to combine a Bash script and Perl script within the same file. Depending on how the script is invoked, either the Bash part or the Perl part will execute.

Example 33-7. Bash and Perl scripts combined

```
bash$ bash bashandperl.sh
Greetings from the Bash part of the script.

bash$ perl -x bashandperl.sh
Greetings from the Perl part of the script.
```

Notes

<u>Prev</u>

Quite a number of Linux utilities are, in fact, shell wrappers. Some examples are /usr/bin/pdf2ps, /usr/bin/batch, and /usr/X11R6/bin/xmkmf.

33.4. Tests and Comparisons: Alternatives

For tests, the $[\]$ construct may be more appropriate than $[\]$. Likewise, arithmetic comparisons might benefit from the $((\))$ construct.

```
1 a=8
 3 # All of the comparisons below are equivalent.
 4 test "$a" -lt 16 && echo "yes, $a < 16"
                                                   # "and list"
 5 /bin/test "$a" -lt 16 && echo "yes, $a < 16"
 6 [ "$a" -lt 16 ] && echo "yes, $a < 16"
 7 [[ $a -lt 16 ]] && echo "yes, $a < 16"
                                                   # Quoting variables within
 8 (( a < 16 )) && echo "yes, $a < 16"
                                                  # [[ ]] and (( )) not necessary.
10 city="New York"
11 # Again, all of the comparisons below are equivalent.
12 test "$city" \< Paris && echo "Yes, Paris is greater than $city"
                                     # Greater ASCII order.
14 /bin/test "$city" \< Paris && echo "Yes, Paris is greater than $city"
15 [ "$city" \< Paris ] && echo "Yes, Paris is greater than $city"
16 [[ $city < Paris ]] && echo "Yes, Paris is greater than $city"
17
                                     # Need not quote $city.
18
19 # Thank you, S.C.
```

Shell Wrappers Up Recursion
Advanced Bash-Scripting Guide: An in-depth exploration of the art of shell scripting

Prev Chapter 33. Miscellany Next

33.5. Recursion

Can a script recursively call itself? Indeed.

Example 33-8. A (useless) script that recursively calls itself

```
1 #!/bin/bash
 2 # recurse.sh
 4 # Can a script recursively call itself?
 5 # Yes, but is this of any practical use?
 6 # (See the following.)
 8 RANGE=10
 9 MAXVAL=9
10
11 i=$RANDOM
12 let "i %= $RANGE" # Generate a random number between 0 and $RANGE - 1.
13
14 if [ "$i" -lt "$MAXVAL" ]
15 then
16 echo "i = $i"
17 ./$0
                      # Script recursively spawns a new instance of itself.
18 fi
                      # Each child script does the same, until
19
                     #+ a generated $i equals $MAXVAL.
20
21 # Using a "while" loop instead of an "if/then" test causes problems.
22 # Explain why.
23
24 exit 0
25
26 # Note:
28 # This script must have execute permission for it to work properly.
29 # This is the case even if it is invoked by an "sh" command.
30 # Explain why.
```

Example 33-9. A (useful) script that recursively calls itself

```
1 #!/bin/bash
 2 # pb.sh: phone book
 4 # Written by Rick Boivie, and used with permission.
 5 # Modifications by ABS Guide author.
 7 MINARGS=1 # Script needs at least one argument.
 8 DATAFILE=./phonebook
              # A data file in current working directory
                #+ named "phonebook" must exist.
10
11 PROGNAME=$0
12 E_NOARGS=70 # No arguments error.
14 if [ $# -lt $MINARGS ]; then
       echo "Usage: "$PROGNAME" data-to-look-up"
16
        exit $E_NOARGS
17 fi
18
```

```
19
20 if [ $# -eq $MINARGS ]; then
          grep $1 "$DATAFILE"
          # 'grep' prints an error message if $DATAFILE not present.
          ( shift; "$PROGNAME" $* ) | grep $1
25
           # Script recursively calls itself.
26 fi
27
28 exit 0 # Script exits here.
                    # Therefore, it's o.k. to put
29
30
                    #+ non-hashmarked comments and data after this point.
31
32 # -----
33 Sample "phonebook" datafile:
35 John Doe 1555 Main St., Baltimore, MD 21228 (410) 222-3333 36 Mary Moe 9899 Jones Blvd., Warren, NH 03787 (603) 898-3232 37 Richard Roe 856 E. 7th St., New York, NY 10009 (212) 333-4567 38 Sam Roe 956 E. 8th St., New York, NY 10009 (212) 444-5678 39 Zoe Zenobia 4481 N. Baker St., San Francisco, SF 94338 (415) 501-1631
40 # -----
41
42 $bash pb.sh Roe
43 Richard Roe 856 E. 7th St., New York, NY 10009 (212) 333-4567
44 Sam Roe
                     956 E. 8th St., New York, NY 10009
                                                                           (212) 444-5678
4.5
46 $bash pb.sh Roe Sam
47 Sam Roe 956 E. 8th St., New York, NY 10009
                                                                          (212) 444-5678
49 # When more than one argument is passed to this script,
50 \#+ it prints *only* the line(s) containing all the arguments.
```

Example 33-10. Another (useful) script that recursively calls itself

```
1 #!/bin/bash
2 # usrmnt.sh, written by Anthony Richardson
3 # Used with permission.
5 # usage: usrmnt.sh
 6 # description: mount device, invoking user must be listed in the
 7 #
                MNTUSERS group in the /etc/sudoers file.
8
9 # -----
10 # This is a usermount script that reruns itself using sudo.
11 # A user with the proper permissions only has to type
12
13 # usermount /dev/fd0 /mnt/floppy
14
15 # instead of
16
17 # sudo usermount /dev/fd0 /mnt/floppy
18
19 # I use this same technique for all of my
20 #+ sudo scripts, because I find it convenient.
21 # -----
23 # If SUDO_COMMAND variable is not set we are not being run through
24 #+ sudo, so rerun ourselves. Pass the user's real and group id . . .
2.5
26 if [ -z "$SUDO_COMMAND" ]
27 then
```

```
mntusr=$(id -u) grpusr=$(id -g) sudo $0 $*
29 exit 0
30 fi
31
32 # We will only get here if we are being run by sudo.
33 /bin/mount $* -o uid=$mntusr,gid=$grpusr
34
35 exit 0
36
37 # Additional notes (from the author of this script):
38 # --
39
40 \# 1) Linux allows the "users" option in the /etc/fstab
41 #
       file so that any user can mount removable media.
       But, on a server, I like to allow only a few
       individuals access to removable media.
     I find using sudo gives me more control.
46 # 2) I also find sudo to be more convenient than
47 # accomplishing this task through groups.
48
49 \# 3) This method gives anyone with proper permissions
50 # root access to the mount command, so be careful
       about who you allow access.
52 #
       You can get finer control over which access can be mounted
       by using this same technique in separate mntfloppy, mntcdrom,
54 # and mntsamba scripts.
```

1 Too many levels of recursion can exhaust the script's stack space, causing a segfault.

Prev **Next Home** <u>Up</u> "Colorizing" Scripts

Tests and Comparisons:

Alternatives

Advanced Bash-Scripting Guide: An in-depth exploration of the art of shell scripting

Chapter 33. Miscellany Prev <u>Next</u>

33.6. "Colorizing" Scripts

The ANSI [1] escape sequences set screen attributes, such as bold text, and color of foreground and background. DOS batch files commonly used ANSI escape codes for *color* output, and so can Bash scripts.

Example 33-11. A "colorized" address database

```
1 #!/bin/bash
 2 # ex30a.sh: "Colorized" version of ex30.sh.
 3 # Crude address database
 4
5
 6 clear
                                          # Clear the screen.
8 echo -n "
9 echo -e '\E[37;44m'"\033[1mContact List\033[0m"

Example 33-12. Drawing a box

```
1 #!/bin/bash
2 # Draw-box.sh: Drawing a box using ASCII characters.
4 # Script by Stefano Palmeri, with minor editing by document author.
5 # Minor edits suggested by Jim Angstadt.
6 # Used in the "ABS Guide" with permission.
7
10 ### draw_box function doc ###
12 # The "draw_box" function lets the user
13 #+ draw a box into a terminal.
14 #
15 # Usage: draw_box ROW COLUMN HEIGHT WIDTH [COLOR]
16 \# ROW and COLUMN represent the position
17 #+ of the upper left angle of the box you're going to draw.
18 \# ROW and COLUMN must be greater than 0
19 #+ and less than current terminal dimension.
20 \# HEIGHT is the number of rows of the box, and must be > 0.
21 # HEIGHT + ROW must be <= than current terminal height.
22 \# WIDTH is the number of columns of the box and must be > 0.
23 # WIDTH + COLUMN must be <= than current terminal width.
24 #
25 # E.g.: If your terminal dimension is 20x80,
26 # draw_box 2 3 10 45 is good
27 # draw_box 2 3 19 45 has bad HEIGHT value (19+2 > 20)
28 \# draw\_box 2 3 18 78 has bad WIDTH value (78+3 > 80)
29 #
30 # COLOR is the color of the box frame.
31 # This is the 5th argument and is optional.
32 # 0=black 1=red 2=green 3=tan 4=blue 5=purple 6=cyan 7=white.
33 # If you pass the function bad arguments,
34 #+ it will just exit with code 65,
35 #+ and no messages will be printed on stderr.
36 #
37 # Clear the terminal before you start to draw a box.
38 \# The clear command is not contained within the function.
```

```
39 # This allows the user to draw multiple boxes, even overlapping ones.
41 ### end of draw_box function doc ###

144
145 # Exercise:
146 # -----
147 # Add the option of printing text within the drawn box.
```

The simplest, and perhaps most useful ANSI escape sequence is bold text, \033[1m ... \033[0m. The \033 represents an escape, the "[1" turns on the bold attribute, while the "[0" switches it off. The "m" terminates each term of the escape sequence.

```
bash$ echo -e "\033[1mThis is bold text.\033[0m"
```

A similar escape sequence switches on the underline attribute (on an rxvt and an aterm).

```
bash$ echo -e "\033[4mThis is underlined text.\033[0m"
```

With an **echo**, the −e option enables the escape sequences.

Other escape sequences change the text and/or background color.

```
bash$ echo -e '\E[34;47mThis prints in blue.'; tput sgr0

bash$ echo -e '\E[33;44m'"yellow text on blue background"; tput sgr0
```

```
bash$ echo -e '\E[1;33;44m'"BOLD yellow text on blue background"; tput sgr0
```

(a) It's usually advisable to set the *bold* attribute for light-colored foreground text.

The tput sgr0 restores the terminal settings to normal. Omitting this lets all subsequent output from that particular terminal remain blue.

Since tput sgr0 fails to restore terminal settings under certain circumstances, echo -ne \E[0m may be a better choice.

Use the following template for writing colored text on a colored background.

```
echo -e '\E[COLOR1;COLOR2mSome text goes here.'
```

The "\E[" begins the escape sequence. The semicolon-separated numbers "COLOR1" and "COLOR2" specify a foreground and a background color, according to the table below. (The order of the numbers does not matter, since the foreground and background numbers fall in non-overlapping ranges.) The "m" terminates the escape sequence, and the text begins immediately after that.

Note also that <u>single quotes</u> enclose the remainder of the command sequence following the **echo -e**.

The numbers in the following table work for an rxvt terminal. Results may vary for other terminal emulators.

Color	Foreground	Background
black	30	40
red	31	41
green	32	42
yellow	33	43
blue	34	44
magenta	35	45
cyan	36	46
white	37	47

Example 33-13. Echoing colored text

```
1 #!/bin/bash
2 # color-echo.sh: Echoing text messages in color.
4 # Modify this script for your own purposes.
5 # It's easier than hand-coding color.
7 black='\E[30;47m'
8 red='\E[31;47m'
9 green='\E[32;47m'
10 yellow='\E[33;47m'
11 blue='\E[34;47m'
12 magenta='\E[35;47m'
```

```
13 cyan='\E[36;47m'
14 white='\E[37;47m'
15
16
17 alias Reset="tput sgr0"
                              # Reset text attributes to normal
                               #+ without clearing screen.
19
20
21 cecho ()

59
60 # Exercises:
62 # 1) Add the "bold" attribute to the 'cecho ()' function.
63 # 2) Add options for colored backgrounds.
```

Example 33-14. A "horserace" game

```
9 #
10 # Exercise:
11 # Edit the script to make it run less randomly,
12 #+ set up a fake betting shop . . .
13 # Um . . . um . . . it's starting to remind me of a movie . . .
15 # The script gives each horse a random handicap.
16 # The odds are calculated upon horse handicap
17 #+ and are expressed in European(?) style.
18 \# E.g., odds=3.75 means that if you bet $1 and win,
19 #+ you receive $3.75.
20 #
21 \# The script has been tested with a GNU/Linux OS,
22 #+ using xterm and rxvt, and konsole.
23 # On a machine with an AMD 900 MHz processor,
24 #+ the average race time is 75 seconds.
25 # On faster computers the race time would be lower.
26 # So, if you want more suspense, reset the USLEEP_ARG variable.
27 #
28 # Script by Stefano Palmeri.
30

See also Example A-23 and Example A-40.

1 There is, however, a major problem with all this. ANSI escape sequences are emphatically non-portable. What works fine on some terminal emulators (or the console) may work differently, or not at all, on others. A "colorized" script that looks stunning on the script author's machine may produce unreadable output on someone else's. This greatly compromises the usefulness of "colorizing" scripts, and possibly relegates this technique to the status of a gimmick or even a "toy".

Moshe Jacobson's color utility (http://runslinux.net/projects.html#color) considerably simplifies using ANSI escape sequences. It substitutes a clean and logical syntax for the clumsy constructs just discussed.

Henry/teikedvl has likewise created a utility (http://scriptechocolor.sourceforge.net/) to simplify creation of colorized scripts.

Notes

Ш	ANSI is, of course, the acronym for the American National Standards Institute. This august body	
	establishes and maintains various technical and industrial standards.

<u>Prev</u>	Chapter 33. Miscellany	<u>Next</u>		

33.7. Optimizations

Most shell scripts are quick 'n dirty solutions to non-complex problems. As such, optimizing them for speed is not much of an issue. Consider the case, though, where a script carries out an important task, does it well, but runs too slowly. Rewriting it in a compiled language may not be a palatable option. The simplest fix would be to rewrite the parts of the script that slow it down. Is it possible to apply principles of code optimization even to a lowly shell script?

Check the loops in the script. Time consumed by repetitive operations adds up quickly. If at all possible, remove time-consuming operations from within loops.

Use <u>builtin</u> commands in preference to system commands. Builtins execute faster and usually do not launch a subshell when invoked.

Avoid unnecessary commands, particularly in a pipe.

```
1 cat "$file" | grep "$word"
2
3 grep "$word" "$file"
4
5 # The above command lines have an identical effect,
6 #+ but the second runs faster since it launches one fewer subprocess.
```

The <u>cat</u> command seems especially prone to overuse in scripts.

Use the <u>time</u> and <u>times</u> tools to profile computation-intensive commands. Consider rewriting time-critical code sections in C, or even in assembler.

Try to minimize file I/O. Bash is not particularly efficient at handling files, so consider using more appropriate tools for this within the script, such as <u>awk</u> or <u>Perl</u>.

Write your scripts in a structured, coherent form, so they can be reorganized and tightened up as necessary. Some of the optimization techniques applicable to high-level languages may work for scripts, but others, such as loop unrolling, are mostly irrelevant. Above all, use common sense.

For an excellent demonstration of how optimization can drastically reduce the execution time of a script, see Example 15-45.

<u>Prev</u>	Chapter 33. Miscellany	<u>Next</u>

33.8. Assorted Tips

33.8.1. Ideas for more powerful scripts

You have a problem that you want to solve by writing a Bash script. Unfortunately, you don't know quite where to start. One method is to plunge right in and code those parts of the script that come easily, and write the hard parts as *pseudo-code*.

```
1 #!/bin/bash
3 ARGCOUNT=1
                                # Need name as argument.
4 E_WRONGARGS=65
 6 if [ number-of-arguments is-not-equal-to "$ARGCOUNT" ]
8 # Can't figure out how to code this . . .
9 #+ . . . so write it in pseudo-code.
10
11 then
12 echo "Usage: name-of-script name"
          ^^^^^^^^^ More pseudo-code.
13 #
14 exit $E_WRONGARGS
15 fi
16
17 . . .
18
19 exit 0
20
21
22 # Later on, substitute working code for the pseudo-code.
23
24 # Line 6 becomes:
25 if [ $# -ne "$ARGCOUNT" ]
26
27 # Line 12 becomes:
28 echo "Usage: `basename $0` name"
```

For an example of using pseudo-code, see the Square Root exercise.

To keep a record of which user scripts have run during a particular session or over a number of sessions, add the following lines to each script you want to keep track of. This will keep a continuing file record of the script names and invocation times.

```
1 # Append (>>) following to end of each script tracked.
2
3 whoami>> $SAVE_FILE  # User invoking the script.
4 echo $0>> $SAVE_FILE  # Script name.
5 date>> $SAVE_FILE  # Date and time.
6 echo>> $SAVE_FILE  # Blank line as separator.
7
8 # Of course, SAVE_FILE defined and exported as environmental variable in ~/.bashrc  9 #+ (something like ~/.scripts-run)
```

The >> operator *appends* lines to a file. What if you wish to *prepend* a line to an existing file, that is, to paste it in at the beginning?

```
1 file=data.txt
2 title="***This is the title line of data text file***"
3
4 echo $title | cat - $file >$file.new
```

```
5 # "cat -" concatenates stdout to $file.
6 # End result is
7 #+ to write a new file with $title appended at *beginning*.
```

This is a simplified variant of the <u>Example 18-13</u> script given earlier. And, of course, <u>sed</u> can also do this.

A shell script may act as an embedded command inside another shell script, a *Tcl* or *wish* script, or even a <u>Makefile</u>. It can be invoked as an external shell command in a C program using the <code>system()</code> call, i.e., <code>system("script_name");</code>.

Setting a variable to the contents of an embedded *sed* or *awk* script increases the readability of the surrounding <u>shell wrapper</u>. See <u>Example A-1</u> and <u>Example 14-20</u>.

Put together files containing your favorite and most useful definitions and functions. As necessary, "include" one or more of these "library files" in scripts with either the dot (.) or source command.

```
1 # SCRIPT LIBRARY
 2 # -----
 3
 4 # Note:
 5 # No "#!" here.
 6 # No "live code" either.
 8
 9 # Useful variable definitions
10

                                     # Caution: Max return value = 255.
    E_ARGERR=-999999
 65
 66
 67 if [ -z "$1" ]
                                     # Need arg passed.
 68 then
 69 return $E_ARGERR
                                   # Obvious error value returned.
 70 fi
 71
 72 if [ "$1" -ge 0 ]
                                    # If non-negative,
 73 then
 74
      absval=$1
                                     # stays as-is.
 75 else
                                     # Otherwise,
      let "absval = ((0 - \$1))" # change sign.
 76
 77 fi
 78
 79 return $absval
 80 }
 81
 82
 83 tolower ()
                          # Converts string(s) passed as argument(s)
 84 {
                          #+ to lowercase.
 85
    if [ -z "$1" ]  # If no argument(s) passed,
then  #+ send error message
echo "(null)"  #+ (C-style void-pointer error message)
##+ and return from function.
 86
 87
 88
 89
    fi
 90
 91
 92 echo "$@" | tr A-Z a-z
 93 # Translate all passed arguments ($@).
 94
 95 return
 96
 97 # Use command substitution to set a variable to function output.
 98 # For example:
99 # oldvar="A seT of miXed-caSe LEtTerS"
100 # newvar=`tolower "$oldvar"`
101 # echo "$newvar" # a set of mixed-case letters
102 #
103 # Exercise: Rewrite this function to change lowercase passed argument(s)
      to uppercase ... toupper() [easy].
104 #
105 }
```

Use special-purpose comment headers to increase clarity and legibility in scripts.

```
1 ## Caution.
2 rm -rf *.zzy ## The "-rf" options to "rm" are very dangerous,
3 ##+ especially with wildcards.
4
```

```
5 #+ Line continuation.
6 # This is line 1
7 #+ of a multi-line comment,
8 #+ and this is the final line.
9
10 #* Note.
11
12 #o List item.
13
14 #> Another point of view.
15 while [ "$var1" != "end" ] #> while test "$var1" != "end"
```

A particularly clever use of <u>if-test</u> constructs is for comment blocks.

```
1 #!/bin/bash
 3 COMMENT_BLOCK=
 4 # Try setting the above variable to some value
 5 #+ for an unpleasant surprise.
 7 if [ $COMMENT_BLOCK ]; then
9 Comment block --
10 ==========
11 This is a comment line.
12 This is another comment line.
13 This is yet another comment line.
14 ===========
16 echo "This will not echo."
17
18 Comment blocks are error-free! Whee!
19
20 fi
2.1
22 echo "No more comments, please."
2.3
24 exit 0
```

Compare this with using here documents to comment out code blocks.

Using the <u>\$? exit status variable</u>, a script may test if a parameter contains only digits, so it can be treated as an integer.

```
1 #!/bin/bash
 3 SUCCESS=0
 4 E BADINPUT=65
 6 test "$1" -ne 0 -o "$1" -eq 0 2>/dev/null
 7 # An integer is either equal to 0 or not equal to 0.
8 # 2>/dev/null suppresses error message.
10 if [ $? -ne "$SUCCESS" ]
12 echo "Usage: `basename $0` integer-input"
13 exit $E_BADINPUT
14 fi
15
16 let "sum = $1 + 25"
                                  # Would give error if $1 not integer.
17 echo "Sum = $sum"
19 # Any variable, not just a command line parameter, can be tested this way.
20
21 exit 0
```

The 0 - 255 range for function return values is a severe limitation. Global variables and other workarounds are often problematic. An alternative method for a function to communicate a value back to the main body of the script is to have the function write to stdout (usually with echo) the "return value," and assign this to a variable. This is actually a variant of command substitution.

Example 33-15. Return value trickery

```
1 #!/bin/bash
 2 # multiplication.sh
                                  # Multiplies params passed.
 4 multiply ()
 5 {
                                  # Will accept a variable number of args.
 6
 7
    local product=1
 8
   until [ -z "$1" ]
9
                                # Until uses up arguments passed...
10
11 let "product *= $1"
12
     shift
13 done
14
15 echo $product
                                  # Will not echo to stdout,
16 }
                                 #+ since this will be assigned to a variable.
17
18 mult1=15383; mult2=25211
19 val1=`multiply $mult1 $mult2`
20 echo "$mult1 X $mult2 = $val1"
21
                                  # 387820813
22
23 mult1=25; mult2=5; mult3=20
24 val2=`multiply $mult1 $mult2 $mult3`
25 echo "$mult1 X $mult2 X $mult3 = $val2"
26
                                  # 2500
27
28 mult1=188; mult2=37; mult3=25; mult4=47
29 val3=`multiply $mult1 $mult2 $mult3 $mult4`
30 echo "$mult1 X $mult2 X $mult3 X $mult4 = $val3"
31
                                  # 8173300
32
33 exit 0
```

The same technique also works for alphanumeric strings. This means that a function can "return" a non-numeric value.

```
1 capitalize_ichar ()
                          # Capitalizes initial character
                          #+ of argument string(s) passed.
2 {
3
   string0="$@"
4
                          # Accepts multiple arguments.
5
6
   firstchar=${string0:0:1} # First character.
7
   string1=${string0:1}
                          # Rest of string(s).
8
9
   FirstChar=`echo "$firstchar" | tr a-z A-Z`
10
                          # Capitalize first character.
11
12
   echo "$FirstChar$string1" # Output to stdout.
13
14 }
15
16 newstring=`capitalize_ichar "every sentence should start with a capital letter."`
```

Example 33-16. Even more return value trickery

```
1 #!/bin/bash
 2 # sum-product.sh
 3 # A function may "return" more than one value.
 5 sum_and_product () # Calculates both sum and product of passed args.
 7 echo $(( $1 + $2 )) $(( $1 * $2 ))
8 # Echoes to stdout each calculated value, separated by space.
1.0
11 echo
12 echo "Enter first number "
13 read first
15 echo
16 echo "Enter second number "
17 read second
18 echo
19
20 retval=`sum_and_product $first $second`  # Assigns output of function.
21 sum=`echo "$retval" | awk '{print $1}'`  # Assigns first field.
22 product=`echo "$retval" | awk '{print $2}'` # Assigns second field.
24 echo "$first + $second = $sum"
25 echo "$first * $second = $product"
26 echo
27
28 exit 0
```

Next in our bag of tricks are techniques for passing an <u>array</u> to a <u>function</u>, then "returning" an array back to the main body of the script.

Passing an array involves loading the space-separated elements of the array into a variable with <u>command substitution</u>. Getting an array back as the "return value" from a function uses the previously mentioned strategem of <u>echoing</u> the array in the function, then invoking command substitution and the (...) operator to assign it to an array.

Example 33-17. Passing and returning arrays

```
1 #!/bin/bash
2 # array-function.sh: Passing an array to a function and...
3 # "returning" an array from a function
4
5
6 Pass_Array ()
7 {
8  local passed_array # Local variable.
9  passed_array=( `echo "$1"` )
10  echo "${passed_array[@]}"
11  # List all the elements of the new array
12  #+ declared and set within the function.
13 }
14
15
```

```
16 original_array=( element1 element2 element3 element4 element5 )
17
18 echo
19 echo "original_array = ${original_array[@]}"
20 #
                       List all elements of original array.
21
22
23 # This is the trick that permits passing an array to a function.
25 argument=`echo ${original_array[@]}`
26 # *****
27 # Pack a variable
28 #+ with all the space-separated elements of the original array.
29 #
30 # Note that attempting to just pass the array itself will not work.
31
32
33 # This is the trick that allows grabbing an array as a "return value".
35 returned_array=( `Pass_Array "$argument"` )
37 # Assign 'echoed' output of function to array variable.
38
39 echo "returned_array = ${returned_array[@]}"
40
42.
43 # Now, try it again,
44 #+ attempting to access (list) the array from outside the function.
45 Pass_Array "$argument"
46
47 # The function itself lists the array, but...
48 #+ accessing the array from outside the function is forbidden.
49 echo "Passed array (within function) = ${passed_array[@]}"
50 # NULL VALUE since this is a variable local to the function.
51
52 echo
53
54 exit 0
```

For a more elaborate example of passing arrays to functions, see Example A-10.

- Using the <u>double parentheses construct</u>, it is possible to use C-style syntax for setting and incrementing/decrementing variables and in <u>for</u> and <u>while</u> loops. See <u>Example 10-12</u> and <u>Example 10-17</u>.
- Setting the <u>path</u> and <u>umask</u> at the beginning of a script makes it more "portable" -- more likely to run on a "foreign" machine whose user may have bollixed up the \$PATH and **umask**.

```
1 #!/bin/bash
2 PATH=/bin:/usr/bin:/usr/local/bin; export PATH
3 umask 022 # Files that the script creates will have 755 permission.
4
5 # Thanks to Ian D. Allen, for this tip.
```

A useful scripting technique is to *repeatedly* feed the output of a filter (by piping) back to the *same filter*, but with a different set of arguments and/or options. Especially suitable for this are <u>tr</u> and <u>grep</u>.

```
1 # From "wstrings.sh" example.
2
3 wlist=`strings "$1" | tr A-Z a-z | tr '[:space:]' Z | \
4 tr -cs '[:alpha:]' Z | tr -s '\173-\377' Z | tr Z ' '`
```

Example 33-18. Fun with anagrams

```
1 #!/bin/bash
 2 # agram.sh: Playing games with anagrams.
 4 # Find anagrams of...
 5 LETTERSET=etaoinshrdlu
 6 FILTER='....' # How many letters minimum?
           1234567
 9 anagram "$LETTERSET" | # Find all anagrams of the letterset...
10 grep "$FILTER" | # With at least 7 letters,
11 grep '^is' |
                          # starting with 'is'
12 grep -v 's$' | # no plurals
13 grep -v 'ed$' # no past tense verbs
14 # Possible to add many combinations of conditions and filters.
15
16 # Uses "anagram" utility
17 #+ that is part of the author's "yawl" word list package.
18 # http://ibiblio.org/pub/Linux/libs/yawl-0.3.2.tar.gz
19 # http://personal.riverusers.com/~thegrendel/yawl-0.3.2.tar.gz
2.0
21 exit 0
                          # End of code.
22
23
24 bash$ sh agram.sh
25 islander
26 isolate
27 isolead
28 isotheral
29
30
31
32 # Exercises:
33 #
34 # Modify this script to take the LETTERSET as a command-line parameter.
35 # Parameterize the filters in lines 11 - 13 (as with $FILTER),
36 #+ so that they can be specified by passing arguments to a function.
38 # For a slightly different approach to anagramming,
39 #+ see the agram2.sh script.
```

See also Example 27-3, Example 15-24, and Example A-9.

- Use "anonymous here documents" to comment out blocks of code, to save having to individually comment out each line with a #. See Example 18-11.
- Running a script on a machine that relies on a command that might not be installed is dangerous. Use <u>whatis</u> to avoid potential problems with this.

```
1 CMD=command1  # First choice.
2 PlanB=command2  # Fallback option.
3
4 command_test=$(whatis "$CMD" | grep 'nothing appropriate')
5 # If 'command1' not found on system , 'whatis' will return
6 #+ "command1: nothing appropriate."
7 #
8 # A safer alternative is:
9 # command_test=$(whereis "$CMD" | grep \/)
10 # But then the sense of the following test would have to be reversed,
11 #+ since the $command_test variable holds content only if
```

```
12 #+ the $CMD exists on the system.

13 # (Thanks, bojster.)

14

15

16 if [[ -z "$command_test" ]] # Check whether command present.

17 then

18 $CMD option1 option2 # Run command1 with options.

19 else # Otherwise,

20 $PlanB #+ run command2.

21 fi
```

An <u>if-grep test</u> may not return expected results in an error case, when text is output to stderr, rather that stdout.

```
1 if ls -l nonexistent_filename | grep -q 'No such file or directory'
2 then echo "File \"nonexistent_filename\" does not exist."
3 fi
```

Redirecting stderr to stdout fixes this.

• If you absolutely must access a subshell variable outside the subshell, here's a way to do it.

```
1 TMPFILE=tmpfile
                                       # Create a temp file to store the variable.
  3 ( # Inside the subshell ...
  4 inner_variable=Inner
  5 echo $inner_variable
  6 echo $inner_variable >>$TMPFILE # Append to temp file.
  9
       # Outside the subshell ...
 10
 11 echo; echo "----"; echo
 12 echo $inner_variable
                                     # Null, as expected.
 13 echo "----"; echo
 14
 15 # Now ...
 16 read inner_variable <$TMPFILE # Read back shell variable.
17 rm -f "$TMPFILE" # Get rid of temp file.
18 echo "$inner_variable" # It's an ugly kludge, but it works.
```

The <u>run-parts</u> command is handy for running a set of command scripts in a particular sequence, especially in combination with <u>cron</u> or <u>at</u>.

For doing multiple revisions on a complex script, use the *rcs* Revision Control System package.

Among other benefits of this is automatically updated ID header tags. The **co** command in *rcs* does a parameter replacement of certain reserved key words, for example, replacing #SIdS in a script with something like:

```
1 #$Id: hello-world.sh,v 1.1 2004/10/16 02:43:05 bozo Exp $
```

33.8.2. Widgets

It would be nice to be able to invoke X-Windows widgets from a shell script. There happen to exist several packages that purport to do so, namely Xscript, Xmenu, and widtools. The first two of these no longer seem to be maintained. Fortunately, it is still possible to obtain widtools here.

The widtools (widget tools) package requires the XForms library to be installed. Additionally, the <u>Makefile</u> needs some judicious editing before the package will build on a typical Linux system. Finally, three of the six widgets offered do not work (and, in fact, segfault).

The dialog family of tools offers a method of calling "dialog" widgets from a shell script. The original dialog utility works in a text console, but its successors, gdialog, Xdialog, and kdialog use X-Windows-based widget sets.

Example 33-19. Widgets invoked from a shell script

```
1 #!/bin/bash
2 # dialog.sh: Using 'gdialog' widgets.
4 # Must have 'gdialog' installed on your system to run this script.
 5 # Or, you can replace all instance of 'gdialog' below with 'kdialog' ...
 6 # Version 1.1 (corrected 04/05/05)
8 # This script was inspired by the following article.
     "Scripting for X Productivity," by Marco Fioretti,
         LINUX JOURNAL, Issue 113, September 2003, pp. 86-9.
10 #
11 # Thank you, all you good people at LJ.
12
13
14 # Input error in dialog box.
15 E_INPUT=65
16 # Dimensions of display, input widgets.
17 HEIGHT=50
18 WIDTH=60
19
20 # Output file name (constructed out of script name).
21 OUTFILE=$0.output
23 # Display this script in a text widget.
24 gdialog --title "Displaying: $0" --textbox $0 $HEIGHT $WIDTH
2.5
2.6
2.7
28 # Now, we'll try saving input in a file.
29 echo -n "VARIABLE=" > $OUTFILE
30 gdialog --title "User Input" --inputbox "Enter variable, please:" \
31 $HEIGHT $WIDTH 2>> $OUTFILE
32
33
34 if [ "$?" -eq 0 ]
35 # It's good practice to check exit status.
36 then
   echo "Executed \"dialog box\" without errors."
37
38 else
39 echo "Error(s) in \"dialog box\" execution."
40
     # Or, clicked on "Cancel", instead of "OK" button.
41 rm $OUTFILE
42 exit $E_INPUT
43 fi
```

```
44
45
46
47 # Now, we'll retrieve and display the saved variable.
48 . $OUTFILE # 'Source' the saved file.
49 echo "The variable input in the \"input box\" was: "$VARIABLE""
50
51
52 rm $OUTFILE # Clean up by removing the temp file.
53 # Some applications may need to retain this file.
54
55 exit $?
56
57 # Exercise: Rewrite this script using the 'zenity' widget set.
```

The <u>xmessage</u> command is a simple method of popping up a message/query window. For example:

```
1 xmessage Fatal error in script! -button exit
```

The latest entry in the widget sweepstakes is <u>zenity</u>. This utility pops up *GTK*+ dialog widgets-and-windows, and it works very nicely within a script.

```
1 get_info ()
 2 {
 3
   zenity --entry
                          # Pops up query window . . .
 4
                          #+ and prints user entry to stdout.
 5
                          # Also try the --calendar and --scale options.
 6
 7 }
 8
 9 answer=$( get_info )
                          # Capture stdout in $answer variable.
10
11 echo "User entered: "$answer""
```

For other methods of scripting with widgets, try *Tk* or *wish* (*Tcl* derivatives), *PerlTk* (*Perl* with *Tk* extensions), *tksh* (*ksh* with *Tk* extensions), *XForms4Perl* (*Perl* with *XForms* extensions), *Gtk-Perl* (*Perl* with *Gtk* extensions), or *PyQt* (*Python* with *Qt* extensions).

Advanced Bash-Scripting Guide: An in-depth exploration of the art of shell scripting

<u>Prev</u> Chapter 33. Miscellany <u>Next</u>

33.9. Security Issues

33.9.1. Infected Shell Scripts

A brief warning about script security is appropriate. A shell script may contain a worm, trojan, or even a virus. For that reason, never run as root a script (or permit it to be inserted into the system startup scripts in /etc/rc.d) unless you have obtained said script from a trusted source or you have carefully analyzed it to make certain it does nothing harmful.

Various researchers at Bell Labs and other sites, including M. Douglas McIlroy, Tom Duff, and Fred Cohen have investigated the implications of shell script viruses. They conclude that it is all too easy for even a novice, a "script kiddie", to write one. [1]

Here is yet another reason to learn scripting. Being able to look at and understand scripts may protect your system from being hacked or damaged.

33.9.2. Hiding Shell Script Source

For security purposes, it may be necessary to render a script unreadable. If only there were a utility to create a stripped binary executable from a script. Francisco Rosales' she -- generic shell script compiler does exactly that.

Unfortunately, according to an article in the October, 2005 *Linux Journal*, the binary can, in at least some cases, be decrypted to recover the original script source. Still, this could be a useful method of keeping scripts secure from all but the most skilled hackers.

33.9.3. Writing Secure Shell Scripts

Dan Stromberg suggests the following guidelines for writing (relatively) secure shell scripts.

- Don't put data that needs to be secret in <u>environment variables</u>.
- Don't pass data that needs to be secret in an external command's arguments (pass them in via a pipe or redirection instead).
- Set your \$PATH carefully. Don't just trust whatever path you inherit from the caller if your script is running as root. In fact, whenever you use an environment variable inherited from the caller, think about what could happen if the caller put something misleading in the variable, e.g., if the caller set **\$HOME** to /etc.

Notes

[1] See Marius van Oers' article, Unix Shell Scripting Malware, and also the *Denning* reference in the bibliography.

Prev Home Next Assorted Tips <u>Up</u> Portability Issues Advanced Bash-Scripting Guide: An in-depth exploration of the art of shell scripting Next

Chapter 33. Miscellany <u>Prev</u>

33.10. Portability Issues

This book deals specifically with Bash scripting on a GNU/Linux system. All the same, users of **sh** and **ksh** will find much of value here.

As it happens, many of the various shells and scripting languages seem to be converging toward the POSIX 1003.2 standard. Invoking Bash with the -posix option or inserting a **set -o posix** at the head of a script causes Bash to conform very closely to this standard. Another alternative is to use a

1 #!/bin/sh

header in the script, rather than

1 #!/bin/bash

Note that /bin/sh is a <u>link</u> to /bin/bash in Linux and certain other flavors of UNIX, and a script invoked this way disables extended Bash functionality.

Most Bash scripts will run as-is under **ksh**, and vice-versa, since Chet Ramey has been busily porting **ksh** features to the latest versions of Bash.

On a commercial UNIX machine, scripts using GNU-specific features of standard commands may not work. This has become less of a problem in the last few years, as the GNU utilities have pretty much displaced their proprietary counterparts even on "big-iron" UNIX. <u>Caldera's release of the source</u> to many of the original UNIX utilities has accelerated the trend.

Bash has certain features that the traditional Bourne shell lacks. Among these are:

- Certain extended invocation options
- Command substitution using \$() notation
- Certain string manipulation operations
- Process substitution
- Bash-specific builtins

See the <u>Bash F.A.O.</u> for a complete listing.

33.11. Shell Scripting Under Windows

Even users running *that other* OS can run UNIX-like shell scripts, and therefore benefit from many of the lessons of this book. The <u>Cygwin</u> package from Cygnus and the <u>MKS utilities</u> from Mortice Kern Associates add shell scripting capabilities to Windows.

There have been intimations that a future release of Windows will contain Bash-like command line scripting capabilities, but that remains to be seen.

Portability Issues	<u>Up</u>	Bash, versions 2 and 3
Advanced Bash-Scripting Gui	de: An in-depth explorat	tion of the art of shell scripting
Prev		<u>Next</u>

Chapter 34. Bash, versions 2 and 3

34.1. Bash, version 2

The current version of *Bash*, the one you have running on your machine, is version 2.xx.y or 3.xx.y.

```
bash$ echo $BASH_VERSION
2.05.b.0(1)-release
```

The version 2 update of the classic Bash scripting language added array variables, [1] string and parameter expansion, and a better method of indirect variable references, among other features.

Example 34-1. String expansion

```
1 #!/bin/bash
2
3 # String expansion.
4 # Introduced with version 2 of Bash.
5
6 # Strings of the form $'xxx'
7 #+ have the standard escaped characters interpreted.
8
9 echo $'Ringing bell 3 times \a \a'
10  # May only ring once with certain terminals.
11 echo $'Three form feeds \f \f \f'
12 echo $'10 newlines \n\n\n\n\n\n\n\n\n'
13 echo $'\102\141\163\150' # Bash
14  # Octal equivalent of characters.
15
16 exit 0
```

Example 34-2. Indirect variable references - the new way

```
1 #!/bin/bash
3 # Indirect variable referencing.
4 # This has a few of the attributes of references in C++.
7 a=letter_of_alphabet
8 letter_of_alphabet=z
10 echo "a = $a"
                          # Direct reference.
12 echo "Now a = \{!a\}"
                         # Indirect reference.
13 # The ${!variable} notation is greatly superior to the old "eval var1=\$$var2"
15 echo
16
17 t=table_cell_3
18 table_cell_3=24
19 echo "t = \{!t\}"
                                         # t = 24
20 table_cell_3=387
21 echo "Value of t changed to ${!t}" # 387
23 # This is useful for referencing members of an array or table,
24 #+ or for simulating a multi-dimensional array.
25 # An indexing option (analogous to pointer arithmetic)
```

```
26 #+ would have been nice. Sigh.
27
28 exit 0
```

Example 34-3. Simple database application, using indirect variable referencing

```
1 #!/bin/bash
2 # resistor-inventory.sh
3 # Simple database application using indirect variable referencing.
5 # ----- #
6 # Data
7
8 B1723_value=470
                                                # Ohms
9 B1723_powerdissip=.25
                                                # Watts
10 B1723_colorcode="yellow-violet-brown"
                                                # Color bands
                                                # Where they are
11 B1723_loc=173
                                                # How many
12 B1723_inventory=78
13
14 B1724_value=1000
15 B1724_powerdissip=.25
16 B1724_colorcode="brown-black-red"
17 B1724_loc=24N
18 B1724_inventory=243
19
20 B1725_value=10000
21 B1725_powerdissip=.25
22 B1725_colorcode="brown-black-orange"
23 B1725_loc=24N
24 B1725_inventory=89
25
26 # ========== #
27
28
29 echo
31 PS3='Enter catalog number: '
32
33 echo
34
35 select catalog_number in "B1723" "B1724" "B1725"
36 do
37
   Inv=${catalog_number}_inventory
38 Val=${catalog_number}_value
   Pdissip=${catalog_number}_powerdissip
40 Loc=${catalog_number}_loc
41
   Ccode=${catalog_number}_colorcode
42
43 echo
44 echo "Catalog number $catalog_number:"
45 echo "There are ${!Inv} of [${!Val} ohm / ${!Pdissip} watt] resistors in stock."
46 echo "These are located in bin # ${!Loc}."
47 echo "Their color code is \"${!Ccode}\"."
48
49 break
50 done
51
52 echo; echo
53
54 # Exercises:
55 # -----
56 # 1) Rewrite this script to read its data from an external file.
```

```
57 # 2) Rewrite this script to use arrays,
58 #+ rather than indirect variable referencing.
59 # Which method is more straightforward and intuitive?
60
61
62 # Notes:
63 # -----
64 # Shell scripts are inappropriate for anything except the most simple
65 #+ database applications, and even then it involves workarounds and kludges.
66 # Much better is to use a language with native support for data structures,
67 #+ such as C++ or Java (or even Perl).
68
69 exit 0
```

Example 34-4. Using arrays and other miscellaneous trickery to deal four random hands from a deck of cards

```
1 #!/bin/bash
 3 # Cards:
 4 # Deals four random hands from a deck of cards.
 6 UNPICKED=0
7 PICKED=1
9 DUPE_CARD=99

Notes

[1] Chet Ramey promises associative arrays (a Perl feature) in a future Bash release. As of version 3, this has not yet happened.

PrevHomeNextShell Scripting Under WindowsUpBash, version 3Advanced Bash-Scripting Guide: An in-depth exploration of the art of shell scriptingPrevChapter 34. Bash, versions 2 and 3Next

34.2. Bash, version 3

On July 27, 2004, Chet Ramey released version 3 of Bash. This update fixed quite a number of bugs and added new features.

Some of the more important added features:

A new, more generalized {a..z} brace expansion operator.

```
1 #!/bin/bash
 3 for i in \{1...10\}
 4 # Simpler and more straightforward than
 5 #+ for i in $(seq 10)
 7 echo -n "$i "
 8 done
10 echo
11
12 # 1 2 3 4 5 6 7 8 9 10
1.3
14
15
16 # Or just . . .
17
18 echo {a..z}  # a b c d e f g h i j k l m n o p q r s t u v w x y z 19 echo {z..a}  # z y x w v u t s r q p o n m l k j i h g f e d c b a
                  # Works backwards, too.
20
21 echo {3..-2} # 3 2 1 0 -1 -2
22 echo {X..d} # X Y Z [ ] ^ _ ` a b c d
                   # Shows (some of) the ASCII characters between Z and a,
2.3
                    #+ but don't rely on this type of behavior because . . .
24
25 echo {]..a} # {]..a}
                    # Why?
```

• The \${!array[@]} operator, which expands to all the indices of a given <u>array</u>.

```
1 #!/bin/bash
  3 Array=(element-zero element-one element-two element-three)
  5 echo ${Array[0]} # element-zero
                      # First element of array.
  8 echo ${!Array[@]} # 0 1 2 3
 9
                      # All the indices of Array.
 10
 11 for i in ${!Array[@]}
 12 do
 13 echo ${Array[i]} # element-zero
 14
                      # element-one
 15
                      # element-two
16
                      # element-three
17
                      # All the elements in Array.
18
19 done
```

The =~ Regular Expression matching operator within a <u>double brackets</u> test expression. (Perl has a similar operator.)

Or, more usefully:

For additional examples of using the =~ operator, see <u>Example A-31</u>, <u>Example 18-14</u>, <u>Example A-37</u>, and <u>Example A-26</u>.

The new set -o pipefail option is useful for debugging <u>pipes</u>. If this option is set, then the <u>exit status</u> of a pipe is the exit status of the last command in the pipe to *fail* (return a non-zero value), rather than the actual final command in the pipe.

See Example 15-42.

The update to version 3 of Bash breaks a few scripts that worked under earlier versions. *Test critical legacy scripts to make sure they still work!*

As it happens, a couple of the scripts in the *Advanced Bash Scripting Guide* had to be fixed up (see Example A-21 and Example 9-4, for instance).

34.2.1. Bash, version 3.1

The version 3.1 update of Bash introduces a number of bugfixes and a few minor changes.

• The += operator is now permitted in in places where previously only the = assignment operator was recognized.

```
1 a=1
2 echo $a  # 1
3
4 a+=5  # Won't work under versions of Bash earlier than 3.1.
5 echo $a  # 15
6
```

```
7 a+=Hello
8 echo $a  # 15Hello
```

Here, += functions as a *string concatenation* operator. Note that its behavior in this particular context is different than within a <u>let</u> construct.

```
1 a=1
2 echo $a  # 1
3
4 let a+=5  # Integer arithmetic, rather than string concatenation.
5 echo $a  # 6
6
7 let a+=Hello  # Doesn't "add" anything to a.
8 echo $a  # 6
```

34.2.2. Bash, version 3.2

This is pretty much a bugfix update.

- In *global* parameter substitutions, the pattern no longer anchors at the start of the string.
- The --wordexp option disables process substitution.
- The =~ Regular Expression match operator no longer requires quoting of the pattern within [[...]].
 - 1 In fact, quoting in this context is *not* advisable as it may cause *regex* evaluation to fail. See the <u>Ubuntu Bug List</u> and <u>Wikinerds on Bash syntax</u>.

With Bash version 3.2.25(1), running on Fedora Core, quoting works, but do not assume this will be the case on *your* machine.

Chapter 35. Endnotes

35.1. Author's Note

doce ut discas

(Teach, that you yourself may learn.)

How did I come to write a Bash scripting book? It's a strange tale. It seems that a few years back I needed to learn shell scripting -- and what better way to do that than to read a good book on the subject? I was looking to buy a tutorial and reference covering all aspects of the subject. I was looking for a book that would take difficult concepts, turn them inside out, and explain them in excruciating detail, with well-commented examples. [1] In fact, I was looking for *this very book*, or something much like it. Unfortunately, it didn't exist, and if I wanted it, I'd have to write it. And so, here we are, folks.

This reminds me of the apocryphal story about a mad professor. Crazy as a loon, the fellow was. At the sight of a book, any book -- at the library, at a bookstore, anywhere -- he would become totally obsessed with the idea that he could have written it, should have written it -- and done a better job of it to boot. He would thereupon rush home and proceed to do just that, write a book with the very same title. When he died some years later, he allegedly had several thousand books to his credit, probably putting even Asimov to shame. The books might not have been any good -- who knows -- but does that really matter? Here's a fellow who lived his dream, even if he was obsessed by it, driven by it . . . and somehow I can't help admiring the old coot.

Notes

[1] This is the notorious *flog it to death* technique.

Prev Chapter 35. Endnotes Next

35.2. About the Author

Who is this guy anyhow?

The author claims no credentials or special qualifications, [1] other than a compulsion to write. [2] This book is somewhat of a departure from his other major work, <u>HOW-2 Meet Women: The Shy Man's Guide to Relationships</u>. He has also written the <u>Software-Building HOWTO</u>. Lately, he has been trying his hand at short fiction.

A Linux user since 1995 (Slackware 2.2, kernel 1.2.1), the author has emitted a few software truffles, including the <u>cruft</u> one-time pad encryption utility, the <u>mcalc</u> mortgage calculator, the <u>judge</u> Scrabble® adjudicator, and the <u>yawl</u> word gaming list package. He got his start in programming using FORTRAN IV on a CDC 3800, but is not the least bit nostalgic for those days.

Living in a secluded desert community with wife and orange cat, he cherishes human frailty, especially his own.

Notes

- [1] In fact, the author is a school dropout and has no credentials or qualifications.
- [2] Those who can, do. Those who can't . . . get an MCSE.

Prev Chapter 35. Endnotes Next

35.3. Where to Go For Help

<u>The author</u> will sometimes, if not too busy (and in a good mood), answer general scripting questions. [1] However, if you have a problem getting a specific script to work, you would be well advised to post to the <u>comp.os.unix.shell</u> Usenet newsgroup.

If you need assistance with a schoolwork assignment, read the pertinent sections of this and other reference works. Do your best to solve the problem using your own wits and resources. Please do not waste the author's time. You will get neither help nor sympathy. [2]

Notes

- [1] E-mails from certain spam-infested TLDs (61, 202, 211, 218, 220, etc.) will be trapped by spam filters and deleted unread. If your ISP is located on one of these, please use a Webmail account to contact the author.
- [2] Well, if you absolutely insist, you can try modifying Example A-40 to suit your purposes.

35.4. Tools Used to Produce This Book

35.4.1. Hardware

A used IBM Thinkpad, model 760XL laptop (P166, 104 meg RAM) running Red Hat 7.1/7.3. Sure, it's slow and has a funky keyboard, but it beats the heck out of a No. 2 pencil and a Big Chief tablet.

Update: upgraded to a 770Z Thinkpad (P2-366, 192 meg RAM) running FC3. Anyone feel like donating a later-model laptop to a starving writer <g>?

Update: upgraded to a A31 Thinkpad (P4-1.6, 512 meg RAM) running FC5. No longer starving, and no longer soliciting donations <g>.

35.4.2. Software and Printware

- i. Bram Moolenaar's powerful SGML-aware vim text editor.
- ii. OpenJade, a DSSSL rendering engine for converting SGML documents into other formats.
- iii. Norman Walsh's DSSSL stylesheets.
- iv. *DocBook, The Definitive Guide*, by Norman Walsh and Leonard Muellner (O'Reilly, ISBN 1-56592-580-7). This is still the standard reference for anyone attempting to write a document in Docbook SGML format.

35.5. Credits

Community participation made this project possible. The author gratefully acknowledges that writing this book would have been an impossible task without help and feedback from all you people out there.

<u>Philippe Martin</u> translated the first version (0.1) of this document into DocBook/SGML. While not on the job at a small French company as a software developer, he enjoys working on GNU/Linux documentation and software, reading literature, playing music, and, for his peace of mind, making merry with friends. You may run across him somewhere in France or in the Basque Country, or you can email him at <u>feloy@free.fr</u>.

Philippe Martin also pointed out that positional parameters past \$9 are possible using {bracket} notation. (See Example 4-5).

<u>Stéphane Chazelas</u> sent a long list of corrections, additions, and example scripts. More than a contributor, he had, in effect, for a while taken on the role of **editor** for this document. Merci beaucoup!

Paulo Marcel Coelho Aragao offered many corrections, both major and minor, and contributed quite a number of helpful suggestions.

I would like to especially thank *Patrick Callahan*, *Mike Novak*, and *Pal Domokos* for catching bugs, pointing out ambiguities, and for suggesting clarifications and changes. Their lively discussion of shell scripting and general documentation issues inspired me to try to make this document more readable.

I'm grateful to Jim Van Zandt for pointing out errors and omissions in version 0.2 of this document. He also contributed an instructive <u>example script</u>.

Many thanks to <u>Jordi Sanfeliu</u> for giving permission to use his fine tree script (<u>Example A-17</u>), and to Rick Boivie for revising it.

Likewise, thanks to Michel Charpentier for permission to use his dc factoring script (Example 15-50).

Kudos to Noah Friedman for permission to use his string function script (Example A-19).

Emmanuel Rouat suggested corrections and additions on command substitution and aliases. He also contributed a very nice sample .bashrc file (Appendix K).

<u>Heiner Steven</u> kindly gave permission to use his base conversion script, <u>Example 15-46</u>. He also made a number of corrections and many helpful suggestions. Special thanks.

Rick Boivie contributed the delightfully recursive *pb.sh* script (<u>Example 33-9</u>), revised the *tree.sh* script (<u>Example A-17</u>), and suggested performance improvements for the *monthlypmt.sh* script (<u>Example 15-45</u>).

Florian Wisser enlightened me on some of the fine points of testing strings (see <u>Example 7-6</u>), and on other matters.

Oleg Philon sent suggestions concerning cut and pidof.

Michael Zick extended the <u>empty array</u> example to demonstrate some surprising array properties. He also contributed the *isspammer* scripts (<u>Example 15-40</u> and <u>Example A-30</u>).

Marc-Jano Knopp sent corrections and clarifications on DOS batch files.

Hyun Jin Cha found several typos in the document in the process of doing a Korean translation. Thanks for pointing these out.

Andreas Abraham sent in a long list of typographical errors and other corrections. Special thanks!

Others contributing scripts, making helpful suggestions, and pointing out errors were Gabor Kiss, Leopold Toetsch, Peter Tillier, Marcus Berglof, Tony Richardson, Nick Drage (script ideas!), Rich Bartell, Jess Thrysoee, Adam Lazur, Bram Moolenaar, Baris Cicek, Greg Keraunen, Keith Matthews, Sandro Magi, Albert Reiner, Dim Segebart, Rory Winston, Lee Bigelow, Wayne Pollock, "jipe," "bojster," "nyal," "Hobbit," "Ender," "Little Monster" (Alexis), "Mark," "Patsie," Emilio Conti, Ian. D. Allen, Hans-Joerg Diers, Arun Giridhar, Dennis Leeuw, Dan Jacobson, Aurelio Marinho Jargas, Edward Scholtz, Jean Helou, Chris Martin, Lee Maschmeyer, Bruno Haible, Wilbert Berendsen, Sebastien Godard, Bjön Eriksson, John MacDonald, Joshua Tschida, Troy Engel, Manfred Schwarb, Amit Singh, Bill Gradwohl, E. Choroba, David Lombard, Jason Parker, Steve Parker, Bruce W. Clare, William Park, Vernia Damiano, Mihai Maties, Mark Alexander, Jeremy Impson, Ken Fuchs, Jared Martin, Frank Wang, Sylvain Fourmanoit, Matthew Sage, Matthew Walker, Kenny Stauffer, Filip Moritz, Andrzej Stefanski, Daniel Albers, Stefano Palmeri, Nils Radtke, Jeroen Domburg, Alfredo Pironti, Phil Braham, Bruno de Oliveira Schneider, Stefano Falsetto, Chris Morgan, Walter Dnes, Linc Fessenden, Michael Iatrou, Pharis Monalo, Jesse Gough, Fabian Kreutz, Mark Norman, Harald Koenig, Dan Stromberg, Peter Knowles, Francisco Lobo, Mariusz Gniazdowski, Sebastian Arming, Benno Schulenberg, Tedman Eng, Jochen DeSmet, Juan Nicolas Ruiz, Oliver Beckstein, Achmed Darwish, Richard Neill, Albert Siersema, Omair Eshkenazi, Geoff Lee, JuanJo Ciarlante, Nathan Coulter, Andreas Kühne, and David Lawyer (himself an author of four HOWTOs).

My gratitude to <u>Chet Ramey</u> and Brian Fox for writing *Bash*, and building into it elegant and powerful scripting capabilities.

Very special thanks to the hard-working volunteers at the <u>Linux Documentation Project</u>. The LDP hosts a repository of Linux knowledge and lore, and has, to a large extent, enabled the publication of this book.

Thanks and appreciation to IBM, Red Hat, the <u>Free Software Foundation</u>, and all the good people fighting the good fight to keep Open Source software free and open.

Thanks most of all to my wife, Anita, for her encouragement and emotional support.

35.6. Disclaimer

(This is a variant of the standard <u>LDP</u> disclaimer.)

No liability for the contents of this document can be accepted. Use the concepts, examples and information at your own risk. There may be errors and inaccuracies that could cause you to lose data or damage your system, so *proceed with appropriate caution*. The author takes no responsibility for any damage caused.

As it happens, it is highly unlikely that either you or your system will suffer harm. In fact, the *raison d'etre* of this book is to enable its readers to analyze shell scripts and determine whether they have *unexpected consequences*.

Bibliography

Those who do not understand UNIX are condemned to reinvent it, poorly.

--Henry Spencer

Edited by Peter Denning, *Computers Under Attack: Intruders, Worms, and Viruses*, ACM Press, 1990, 0-201-53067-8.

This compendium contains a couple of articles on shell script viruses.

*

Ken Burtch, Linux Shell Scripting with Bash, 1st edition, Sams Publishing (Pearson), 2004, 0672326426.

Covers much of the same material as this guide. Dead tree media does have its advantages, though.

*

Dale Dougherty and Arnold Robbins, *Sed and Awk*, 2nd edition, O'Reilly and Associates, 1997, 1-156592-225-5.

To unfold the full power of shell scripting, you need at least a passing familiarity with **sed** and **awk**. This is the standard tutorial. It includes an excellent introduction to "regular expressions". Read this book.

*

Jeffrey Friedl, Mastering Regular Expressions, O'Reilly and Associates, 2002, 0-596-00289-0.

Still the best, all-around reference on Regular Expressions.

*

Aeleen Frisch, Essential System Administration, 3rd edition, O'Reilly and Associates, 2002, 0-596-00343-9.

This excellent sys admin manual has a decent introduction to shell scripting for sys administrators and does a nice job of explaining the startup and initialization scripts.

*

Stephen Kochan and Patrick Woods, Unix Shell Programming, Hayden, 1990, 067248448X.

The standard reference, though more than a bit dated by now.

*

Neil Matthew and Richard Stones, Beginning Linux Programming, Wrox Press, 1996, 1874416680.

Surprisingly good in-depth coverage of various programming languages available for Linux, including a fairly strong chapter on shell scripting.

*

Herbert Mayer, Advanced C Programming on the IBM PC, Windcrest Books, 1989, 0830693637.

Excellent coverage of algorithms and general programming practices. Unfortunately, out of print.

*

David Medinets, Unix Shell Programming Tools, McGraw-Hill, 1999, 0070397333.

Good info on shell scripting, with examples, and a short intro to Tcl and Perl.

*

Cameron Newham and Bill Rosenblatt, *Learning the Bash Shell*, 2nd edition, O'Reilly and Associates, 1998, 1-56592-347-2.

This is a valiant effort at a decent shell primer, but somewhat deficient in coverage on programming topics and lacking sufficient examples.

*

Anatole Olczak, Bourne Shell Quick Reference Guide, ASP, Inc., 1991, 093573922X.

A very handy pocket reference, despite lacking coverage of Bash-specific features.

*

Jerry Peek, Tim O'Reilly, and Mike Loukides, *Unix Power Tools*, 2nd edition, O'Reilly and Associates, Random House, 1997, 1-56592-260-3.

Contains a couple of sections of very informative in-depth articles on shell programming, but falls short of being a tutorial. It reproduces much of the regular expressions tutorial from the Dougherty and Robbins book, above. The coverage of UNIX commands makes this book well worth buying.

*

Clifford Pickover, Computers, Pattern, Chaos, and Beauty, St. Martin's Press, 1990, 0-312-04123-3.

A treasure trove of ideas and recipes for computer-based exploration of mathematical oddities.

*

George Polya, How To Solve It, Princeton University Press, 1973, 0-691-02356-5.

The classic tutorial on problem solving methods (i.e., algorithms), with special emphasis on how to teach them.

*

Chet Ramey and Brian Fox, *The GNU Bash Reference Manual*, Network Theory Ltd, 2003, 0-9541617-7-7.

This manual is the definitive reference for GNU Bash. The authors of this manual, Chet Ramey and Brian Fox, are the original developers of GNU Bash. For each copy sold the publisher donates \$1 to the Free Software Foundation.

Arnold Robbins, Bash Reference Card, SSC, 1998, 1-58731-010-5.

Excellent Bash pocket reference (don't leave home without it, especially if you're a sysadmin). A bargain at \$4.95, but also available for free download <u>on-line</u> in pdf format.

*

Arnold Robbins, *Effective Awk Programming*, Free Software Foundation / O'Reilly and Associates, 2000, 1-882114-26-4.

The absolute best *awk* tutorial and reference. The free electronic version of this book is part of the *awk* documentation, and printed copies of the latest version are available from O'Reilly and Associates.

This book has served as an inspiration for the author of the ABS Guide.

*

Bill Rosenblatt, Learning the Korn Shell, O'Reilly and Associates, 1993, 1-56592-054-6.

This well-written book contains some excellent pointers on shell scripting in general.

*

Paul Sheer, LINUX: Rute User's Tutorial and Exposition, 1st edition, , 2002, 0-13-033351-4.

Very detailed and readable introduction to Linux system administration.

The book is available in print, or <u>on-line</u>.

*

Ellen Siever and the staff of O'Reilly and Associates, *Linux in a Nutshell*, 2nd edition, O'Reilly and Associates, 1999, 1-56592-585-8.

The all-around best Linux command reference. It even has a Bash section.

Dave Taylor, *Wicked Cool Shell Scripts: 101 Scripts for Linux, Mac OS X, and Unix Systems*, 1st edition, No Starch Press, 2004, 1-59327-012-7.

Just as the title says . . .

*

The UNIX CD Bookshelf, 3rd edition, O'Reilly and Associates, 2003, 0-596-00392-7.

An array of seven UNIX books on CD ROM, including *UNIX Power Tools*, *Sed and Awk*, and *Learning the Korn Shell*. A complete set of all the UNIX references and tutorials you would ever need at about \$130. Buy this one, even if it means going into debt and not paying the rent.

Update: Seems to have somehow gotten out of print.

*

The O'Reilly books on Perl. (Actually, any O'Reilly books.)

Fioretti, Marco, "Scripting for X Productivity," *Linux Journal*, Issue 113, September, 2003, pp. 86-9.

Ben Okopnik's well-written *introductory Bash scripting* articles in issues 53, 54, 55, 57, and 59 of the *Linux Gazette*, and his explanation of "The Deep, Dark Secrets of Bash" in issue 56.

Chet Ramey's *bash* - *The GNU Shell*, a two-part series published in issues 3 and 4 of the *Linux Journal*, July-August 1994.

Mike G's Bash-Programming-Intro HOWTO.

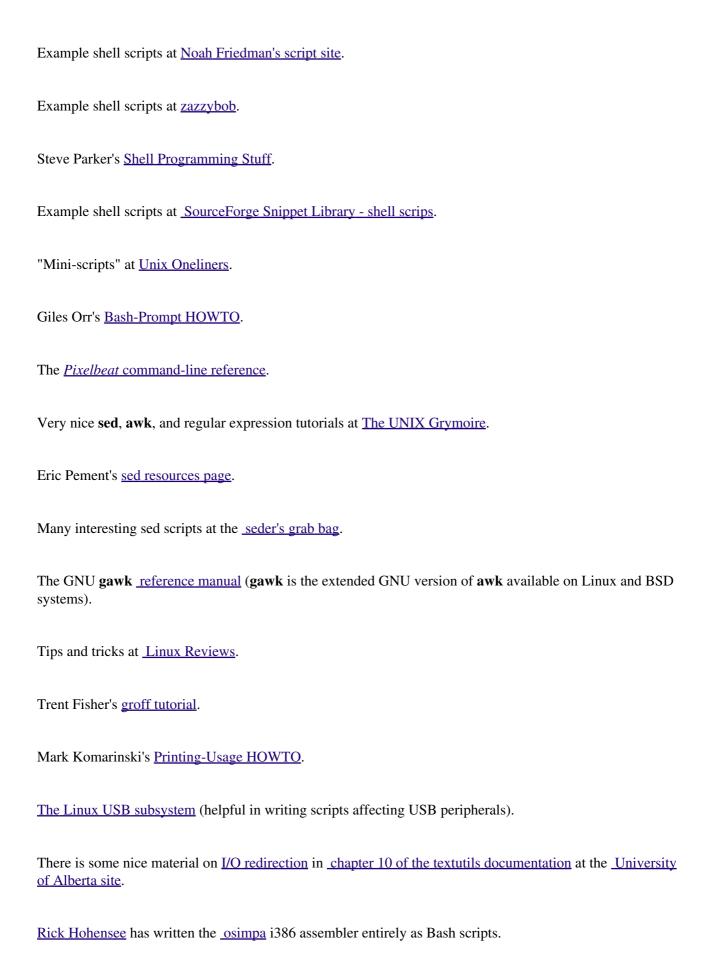

Richard's **Unix Scripting Universe**.

Chet Ramey's <u>Bash FAQ</u>. This site carries the latest version of the FAQ.

Ed Schaefer's Shell Corner in Unix Review.

Example shell scripts at Lucc's Shell Scripts.

Example shell scripts at **SHELLdorado**.

Aurelio Marinho Jargas has written a <u>Regular expression wizard</u>. He has also written an informative <u>book</u> on Regular Expressions, in Portuguese.

Ben Tomkins has created the Bash Navigator directory management tool.

<u>William Park</u> has been working on a <u>project</u> to incorporate certain *Awk* and *Python* features into Bash. Among these is a *gdbm* interface. He has released <u>bashdiff</u> on <u>Freshmeat.net</u>. He has an <u>article</u> in the November, 2004 issue of the <u>Linux Gazette</u> on adding string functions to Bash, with a <u>followup article</u> in the December issue, and <u>yet another</u> in the January, 2005 issue.

Peter Knowles has written an <u>elaborate Bash script</u> that generates a book list on the <u>Sony Librie</u> e-book reader. This useful tool permits loading non-DRM user content on the *Librie* (and the newer *PRS-50X-series* devices).

Tim Waugh's xmlto is an elaborate Bash script for converting Docbook XML documents to other formats.

Of historical interest are Colin Needham's <u>original International Movie Database (IMDB)</u> reader polling <u>scripts</u>, which nicely illustrate the use of <u>awk</u> for string parsing. Unfortunately, the URL link no longer works.

Fritz Mehner has written a <u>bash-support plugin</u> for the *vim* text editor. He has also also come up with his own <u>stylesheet for Bash</u>. Compare it with the <u>ABS Guide Unofficial Stylesheet</u>.

The excellent *Bash Reference Manual*, by Chet Ramey and Brian Fox, distributed as part of the "bash-2-doc" package (available as an rpm). See especially the instructive example scripts in this package.

The <u>comp.os.unix.shell</u> newsgroup.

The dd thread on Linux Questions.

The comp.os.unix.shell FAQ and its mirror site.

Assorted comp.os.unix <u>FAQs</u>.

The <u>manpages</u> for bash and bash2, date, expect, expr, find, grep, gzip, ln, patch, tar, tr, bc, xargs. The texinfo documentation on bash, dd, m4, gawk, and sed.

Appendix A. Contributed Scripts

These scripts, while not fitting into the text of this document, do illustrate some interesting shell programming techniques. They are useful, too. Have fun analyzing and running them.

Example A-1. mailformat: Formatting an e-mail message

```
1 #!/bin/bash
 2 # mail-format.sh (ver. 1.1): Format e-mail messages.
 4 # Gets rid of carets, tabs, and also folds excessively long lines.
 Standard Check for Script Argument(s)
 8 ARGS=1
9 E_BADARGS=65
10 E_NOFILE=66
11
12 if [ $# -ne $ARGS ] # Correct number of arguments passed to script?
14 echo "Usage: `basename $0` filename"
15 exit $E_BADARGS
16 fi
17
18 if [ -f "$1" ]  # Check if file exists.
19 then
file_name=$1
21 else
22 echo "File \"$1\" does not exist."
23
     exit $E_NOFILE
24 fi
27 MAXWIDTH=70
                   # Width to fold excessively long lines to.
30 # A variable can hold a sed script.
31 sedscript='s/^>//
32 s/^ *>//
33 s/^ *//
34 s/ *//'
35 # -----
37 # Delete carets and tabs at beginning of lines,
38 #+ then fold lines to $MAXWIDTH characters.
39 sed "$sedscript" $1 | fold -s --width=$MAXWIDTH
                       # -s option to "fold"
41
                       #+ breaks lines at whitespace, if possible.
43
44 # This script was inspired by an article in a well-known trade journal
45 #+ extolling a 164K MS Windows utility with similar functionality.
47 # An nice set of text processing utilities and an efficient
48 #+ scripting language provide an alternative to bloated executables.
50 exit 0
```

This script is a modification of Example 15-21.

```
1 #! /bin/bash
3 # Very simpleminded filename "rename" utility (based on "lowercase.sh").
5 # The "ren" utility, by Vladimir Lanin (lanin@csd2.nyu.edu),
6 #+ does a much better job of this.
8
9 ARGS=2
10 E BADARGS=65
11 ONE=1
                            # For getting singular/plural right (see below).
12
13 if [ $# -ne "$ARGS" ]

38 echo "$number files renamed."
39 fi
40
41 exit 0
42
43
44 # Exercises:
45 # -----
46 # What type of files will this not work on?
47 # How can this be fixed?
48 #
49 # Rewrite this script to process all the files in a directory
50 #+ containing spaces in their names, and to rename them,
51 #+ substituting an underscore for each space.
```

Example A-3. blank-rename: renames filenames containing blanks

This is an even simpler-minded version of previous script.

```
1 #! /bin/bash
2 # blank-rename.sh
3 #
```

```
4 # Substitutes underscores for blanks in all the filenames in a directory.
                         # For getting singular/plural right (see below).
 6 ONE=1
 7 number=0
                         # Keeps track of how many files actually renamed.
8 FOUND=0
                         # Successful return value.
10 for filename in *
                  #Traverse all files in directory.
11 do
      echo "$filename" | grep -q " " # Check whether filename
12
      if [ $? -eq $FOUND ]
13
                                        #+ contains space(s).
14
      then
      15
16
       mv "$fname" "$n"
let "number += 1"
17
                                        # Do the actual renaming.
18
19 fi
20 done
21
22 if [ "$number" -eq "$ONE" ] # For correct grammar.
23 then
24 echo "$number file renamed."
25 else
26 echo "$number files renamed."
27 fi
28
29 exit 0
```

Example A-4. encryptedpw: Uploading to an ftp site, using a locally encrypted password

```
1 #!/bin/bash
3 # Example "ex72.sh" modified to use encrypted password.
5 # Note that this is still rather insecure,
 6 #+ since the decrypted password is sent in the clear.
7 # Use something like "ssh" if this is a concern.
9 E_BADARGS=65

Example A-6. Collatz series

```
1 #!/bin/bash
2 # collatz.sh
 4 # The notorious "hailstone" or Collatz series.
 6 # 1) Get the integer "seed" from the command line.
 7 # 2) NUMBER <--- seed
 8 # 3) Print NUMBER.
 9 \# 4) If NUMBER is even, divide by 2, or
10 \# 5)+ if odd, multiply by 3 and add 1.
11 # 6) NUMBER <--- result
12 \# 7) Loop back to step 3 (for specified number of iterations).
13 #
14 # The theory is that every sequence,
15 #+ no matter how large the initial value,
16 #+ eventually settles down to repeating "4,2,1..." cycles,
17 #+ even after fluctuating through a wide range of values.
18 #
19 # This is an instance of an "iterate,"
20 #+ an operation that feeds its output back into the input.
21 # Sometimes the result is a "chaotic" series.
2.2.
23
24 MAX_ITERATIONS=200
25 # For large seed numbers (>32000), increase MAX_ITERATIONS.
27 h=\{1:-\$\}
                                  # Seed
28
                                  # Use $PID as seed,
29
                                  #+ if not specified as command-line arg.

350
351 exit 0 # END
352
353
354
355 # The grid in this script has a "boundary problem."
356 # The the top, bottom, and sides border on a void of dead cells.
357 # Exercise: Change the script to have the grid wrap around,
358 \# + so that the left and right sides will "touch,"
359 # +
             as will the top and bottom.
360 #
361 # Exercise: Create a new "gen0" file to seed this script.
362 \# Use a 12 x 16 grid, instead of the original 10 x 10 one.
363 #
             Make the necessary changes to the script,
364 #+
             so it will run with the altered file.
365 #
366 # Exercise: Modify this script so that it can determine the grid size
        from the "gen0" file, and set any variables necessary
368 #+
             for the script to run.
369 #
             This would make unnecessary any changes to variables
370 \#+ in the script for an altered grid size.
```

Example A-11. Data file for "Game of Life"

```
1 # gen0
 3 # This is an example "generation 0" start-up file for "life.sh".
 5 \# The "gen0" file is a 10 x 10 grid using a period (.) for live cells,
 6 #+ and an underscore (_) for dead ones. We cannot simply use spaces
 7 #+ for dead cells in this file because of a peculiarity in Bash arrays.
    [Exercise for the reader: explain this.]
10 # Lines beginning with a '#' are comments, and the script ignores them.

The following two scripts are by Mark Moraes of the University of Toronto. See the file Moraes-COPYRIGHT for permissions and restrictions. This file is included in the combined https://html/source_html of the ABS Guide.

Example A-12. behead: Removing mail and news message headers

```
1 #! /bin/sh
2 # Strips off the header from a mail/News message i.e. till the first
 3 # empty line
 4 # Mark Moraes, University of Toronto
 6 # ==> These comments added by author of this document.
8 if [ $# -eq 0 ]; then
9 \# ==> If no command line args present, then works on file redirected to stdin.
10
    sed -e '1,/^$/d' -e '/^[ ]*$/d'
11
     # --> Delete empty lines and all lines until
12
     # --> first one beginning with white space.
13 else
14 # ==> If command line args present, then work on files named.
15 for i do
             sed -e '1,/^$/d' -e '/^[
16
                                            ]*$/d' $i
17
             # --> Ditto, as above.
18 done
19 fi
20
21 # ==> Exercise: Add error checking and other options.
22 # ==>
23 # ==> Note that the small sed script repeats, except for the arg passed.
24 \ \# ==>  Does it make sense to embed it in a function? Why or why not?
```

Example A-13. ftpget: Downloading files via ftp

```
1 #! /bin/sh
 2 # $Id: ftpget, v 1.2 91/05/07 21:15:43 moraes Exp $
 3 # Script to perform batch anonymous ftp. Essentially converts a list of
 4 # of command line arguments into input to ftp.
 5 # ==> This script is nothing but a shell wrapper around "ftp" . . .
 6 # Simple, and quick - written as a companion to ftplist
 7 # -h specifies the remote host (default prep.ai.mit.edu)
 8\ \#\ -d specifies the remote directory to cd to - you can provide a sequence
 9 # of -d options - they will be cd'ed to in turn. If the paths are relative,
10 # make sure you get the sequence right. Be careful with relative paths -
11 # there are far too many symlinks nowadays.
12 # (default is the ftp login directory)
13 \# -v turns on the verbose option of ftp, and shows all responses from the
14 # ftp server.
15 # -f remotefile[:localfile] gets the remote file into localfile
16 # -m pattern does an mget with the specified pattern. Remember to quote
17 # shell characters.
18 # -c does a local cd to the specified directory
19 # For example,
20 # ftpget -h expo.lcs.mit.edu -d contrib -f xplaces.shar:xplaces.sh \
              -d ../pub/R3/fixes -c ~/fixes -m 'fix*'
22 # will get xplaces.shar from ~ftp/contrib on expo.lcs.mit.edu, and put it
23 # in xplaces.sh in the current working directory, and get all fixes from
24 # ~ftp/pub/R3/fixes and put them in the ~/fixes directory.
25 # Obviously, the sequence of the options is important, since the equivalent
26 # commands are executed by ftp in corresponding order
28 # Mark Moraes <moraes@csri.toronto.edu>, Feb 1, 1989
29 #

108 # ==> 2) Add bells & whistles.
```

+

Antek Sawicki contributed the following script, which makes very clever use of the parameter substitution operators discussed in <u>Section 9.3</u>.

Example A-14. password: Generating random 8-character passwords

```
1 #!/bin/bash
2 # May need to be invoked with #!/bin/bash2 on older machines.
 4 # Random password generator for Bash 2.x +
 5 #+ by Antek Sawicki <tenox@tenox.tc>,
 6 #+ who generously gave usage permission to the ABS Guide author.
7 #
8 # ==> Comments added by document author ==>
9
10
11 MATRIX="0123456789ABCDEFGHIJKLMNOPQRSTUVWXYZabcdefqhijklmnopqrstuvwxyz"
12 # ==> Password will consist of alphanumeric characters.
13 LENGTH="8"
14 # ==> May change 'LENGTH' for longer password.
15
16
17 while [ "${n:=1}" -le "$LENGTH" ]
18 # ==> Recall that := is "default substitution" operator.
19 # ==> So, if 'n' has not been initialized, set it to 1.
20 do
2.1
    PASS="$PASS${MATRIX:$(($RANDOM%${#MATRIX})):1}"
2.2.
     # ==> Very clever, but tricky.
2.3
2.4
     # ==> Starting from the innermost nesting...
2.5
     # ==> ${#MATRIX} returns length of array MATRIX.
2.6
2.7
     # ==> $RANDOM%${#MATRIX} returns random number between 1
28
     \# ==>  and [length of MATRIX] - 1.
29
     # ==> ${MATRIX:$(($RANDOM%${#MATRIX})):1}
     # ==> returns expansion of MATRIX at random position, by length 1.
32
     # ==> See {var:pos:len} parameter substitution in Chapter 9.
33
     # ==> and the associated examples.
34
35
      # ==> PASS=... simply pastes this result onto previous PASS (concatenation).
36
37
      # ==> To visualize this more clearly, uncomment the following line
                        echo "$PASS"
38
39
      # ==> to see PASS being built up,
40
      # ==> one character at a time, each iteration of the loop.
41
```

```
42  let n+=1
43  # ==> Increment 'n' for next pass.
44 done
45
46 echo "$PASS"  # ==> Or, redirect to a file, as desired.
47
48 exit 0
```

+

James R. Van Zandt contributed this script, which uses named pipes and, in his words, "really exercises quoting and escaping".

Example A-15. fifo: Making daily backups, using named pipes

```
1 #!/bin/bash
 2 # ==> Script by James R. Van Zandt, and used here with his permission.
 4 # ==> Comments added by author of this document.
 6
 7
   HERE=`uname -n` # ==> hostname
   THERE=bilbo
 8
    echo "starting remote backup to $THERE at `date +%r`"
 9
     # ==> `date +%r` returns time in 12-hour format, i.e. "08:08:34 PM".
10
11
12
     # make sure /pipe really is a pipe and not a plain file
13
    rm -rf /pipe
    mkfifo /pipe
14
                      # ==> Create a "named pipe", named "/pipe".
15
     # ==> 'su xyz' runs commands as user "xyz".
16
    # ==> 'ssh' invokes secure shell (remote login client).
17
    su xyz -c "ssh $THERE \"cat > /home/xyz/backup/${HERE}-daily.tar.gz\" < /pipe"&
18
19
    tar -czf - bin boot dev etc home info lib man root sbin share usr var > /pipe
2.0
21
     # ==> Uses named pipe, /pipe, to communicate between processes:
     # ==> 'tar/gzip' writes to /pipe and 'ssh' reads from /pipe.
23
     # ==> The end result is this backs up the main directories, from / on down.
2.4
2.5
    # ==> What are the advantages of a "named pipe" in this situation,
26
27
     # ==>+ as opposed to an "anonymous pipe", with |?
     # ==> Will an anonymous pipe even work here?
2.8
29
     # ==> Is it necessary to delete the pipe before exiting the script?
30
     # ==> How could that be done?
31
32
33
34 exit 0
```

+

Stéphane Chazelas contributed the following script to demonstrate that generating prime numbers does not require arrays.

Example A-16. Generating prime numbers using the modulo operator

```
1 #!/bin/bash
2 # primes.sh: Generate prime numbers, without using arrays.
3 # Script contributed by Stephane Chazelas.
5 # This does *not* use the classic "Sieve of Eratosthenes" algorithm,
 6 #+ but instead uses the more intuitive method of testing each candidate number
7 #+ for factors (divisors), using the "%" modulo operator.
                                # Primes 2 - 1000
10 LIMIT=1000
11
12 Primes()
13 {
14 ((n = \$1 + 1))
                                # Bump to next integer.
15 shift
                                # Next parameter in list.
16 # echo "_n=$n i=$i_"
17
18 if ((n == LIMIT))
19 then echo $*
20 return
21 fi
22
23 for i; do
                                # "i" gets set to "@", previous values of $n.
24 # echo "-n=$n i=$i-"
     (( i * i > n )) && break
                                # Optimization.
26
     ((n % i )) && continue # Sift out non-primes using modulo operator.
27 Primes $n $@
                               # Recursion inside loop.
28 return
29 done
30
31
    Primes $n $@ $n
                                # Recursion outside loop.
32
                                # Successively accumulate positional parameters.
                                # "$@" is the accumulating list of primes.
33
34 }
35
36 Primes 1
37
38 exit 0
39
40 # Uncomment lines 16 and 24 to help figure out what is going on.
41
42 # Compare the speed of this algorithm for generating primes
43 #+ with the Sieve of Eratosthenes (ex68.sh).
44
45 # Exercise: Rewrite this script without recursion, for faster execution.
```

+

This is Rick Boivie's revision of Jordi Sanfeliu's tree script.

Example A-17. tree: Displaying a directory tree

```
1 #!/bin/bash
2 # tree.sh
3
4 # Written by Rick Boivie.
5 # Used with permission.
6 # This is a revised and simplified version of a script
7 #+ by Jordi Sanfeliu (and patched by Ian Kjos).
8 # This script replaces the earlier version used in
9 #+ previous releases of the Advanced Bash Scripting Guide.
10
11 # ==> Comments added by the author of this document.
```

```
12
13
14 search () {
15 for dir in `echo *`
16 # ==> `echo *` lists all the files in current working directory,
17 #+ ==> without line breaks.
18 # ==> Similar effect to for dir in *
19 # ==> but "dir in `echo *`" will not handle filenames with blanks.
20 do
    if [ -d "$dir" ] ; then # ==> If it is a directory (-d)...

```

Patsie's version of a directory *tree* script.

Example A-18. tree2: Alternate directory tree script

```
1 #!/bin/bash
2 # tree2.sh
3
4 # Lightly modified/reformatted by ABS Guide author.
5 # Included in ABS Guide with permission of script author (thanks!).
6
7 ## Recursive file/dirsize checking script, by Patsie
8 ##
9 ## This script builds a list of files/directories and their size (du -akx)
10 ## and processes this list to a human readable tree shape
```

```
11 ## The 'du -akx' is only as good as the permissions the owner has.
12 ## So preferably run as root* to get the best results, or use only on
13 ## directories for which you have read permissions. Anything you can't
14 ## read is not in the list.
16 #* ABS Guide author advises caution when running scripts as root!
17

Noah Friedman gave permission to use his *string function* script, which essentially reproduces some of the *C*-library string manipulation functions.

Example A-19. string functions: C-style string functions

```
1 #!/bin/bash
 3 # string.bash --- bash emulation of string(3) library routines
 4 # Author: Noah Friedman <friedman@prep.ai.mit.edu>
 5 # ==> Used with his kind permission in this document.
 6 # Created: 1992-07-01
 7 # Last modified: 1993-09-29
 8 # Public domain
10 # Conversion to bash v2 syntax done by Chet Ramey
11
12 # Commentary:
13 # Code:
15 #:docstring strcat:
16 # Usage: strcat s1 s2
17 #
18 # Strcat appends the value of variable s2 to variable s1.
19 #
20 # Example:
21 # a="foo"
22 #
      b="bar"
23 # strcat a b
24 #
      echo $a
25 # => foobar
26 #
27 #:end docstring:

42 # '-of' meaning 'output to filename'
43 # # # # #
45 String format description based on: ls (GNU fileutils) version 4.0.36
46
47 Produces a line (or more) formatted:
48 inode permissions hard-links owner group ...
49 32736 -rw---- 1 mszick
                                mszick
50
51 size
         day month date hh:mm:ss year path
52 2756608 Sun Apr 20 08:53:06 2003 /home/mszick/core
54 Unless it is formatted:
55 inode permissions hard-links owner group ...
56 266705 crw-rw--- 1 root uucp
58 major minor day month date hh:mm:ss year path
59 4, 68 Sun Apr 20 09:27:33 2003 /dev/ttyS4
60 NOTE: that pesky comma after the major number
62 NOTE: the 'path' may be multiple fields:
63 /home/mszick/core
64 /proc/982/fd/0 -> /dev/null
65 /proc/982/fd/1 -> /home/mszick/.xsession-errors
66 /proc/982/fd/13 -> /tmp/tmpfZVVOCs (deleted)
67 /proc/982/fd/7 -> /tmp/kde-mszick/ksycoca
68 /proc/982/fd/8 -> socket:[11586]
69 /proc/982/fd/9 -> pipe:[11588]
70
71 If that isn't enough to keep your parser guessing,
72 either or both of the path components may be relative:
73 ../Built-Shared -> Built-Static
74 ../linux-2.4.20.tar.bz2 -> ../../../SRCS/linux-2.4.20.tar.bz2
75
76 The first character of the 11 (10?) character permissions field:
77 's' Socket
78 'd' Directory
```

```
79 'b' Block device
 80 'c' Character device
 81 'l' Symbolic link
 82 NOTE: Hard links not marked - test for identical inode numbers
 83 on identical filesystems.
 84 All information about hard linked files are shared, except
 85 for the names and the name's location in the directory system.
 86 NOTE: A "Hard link" is known as a "File Alias" on some systems.
 87 '-' An undistingushed file
 88
 89 Followed by three groups of letters for: User, Group, Others
 90 Character 1: '-' Not readable; 'r' Readable
 91 Character 2: '-' Not writable; 'w' Writable
 92 Character 3, User and Group: Combined execute and special
 93 '-' Not Executable, Not Special
 94 'x' Executable, Not Special
 95 's' Executable, Special
 96 'S' Not Executable, Special
 97 Character 3, Others: Combined execute and sticky (tacky?)
 98 '-' Not Executable, Not Tacky
99 'x' Executable, Not Tacky
100 't' Executable, Tacky
101 'T' Not Executable, Tacky
102
103 Followed by an access indicator
104 Haven't tested this one, it may be the eleventh character
105 or it may generate another field
106 ' ' No alternate access
107 '+' Alternate access

167 Walk an array of directory fields produced by ListDirectory
168
169 Having suppressed the line breaks in an otherwise line oriented
170 report, build an index to the array element which starts each line.
172 Each line gets two index entries, the first element of each line
173 (inode) and the element that holds the pathname of the file.
174
175 The first index entry pair (Line-Number==0) are informational:
176 Index-Array-Name[0] : Number of "Lines" indexed
177 Index-Array-Name[1] : "Current Line" pointer into Index-Array-Name
178
179 The following index pairs (if any) hold element indexes into
180 the Field-Array-Name per:
181 Index-Array-Name[Line-Number * 2] : The "inode" field element.
182 NOTE: This distance may be either +11 or +12 elements.
183 Index-Array-Name[(Line-Number * 2) + 1] : The "pathname" element.
184 NOTE: This distance may be a variable number of elements.
185 Next line index pair for Line-Number+1.

274
275 The key (no pun intended) to a Unified Content File System (UCFS)
276 is to distinguish the files in the system based on their content.
```

```
277 Distinguishing files by their name is just, so, 20th Century.
279 The content is distinguished by computing a checksum of that content.
280 This version uses the md5sum program to generate a 128 bit checksum
281 representative of the file's contents.
282 There is a chance that two files having different content might
283 generate the same checksum using md5sum (or any checksum). Should
284 that become a problem, then the use of md5sum can be replace by a
285 cyrptographic signature. But until then...
287 The md5sum program is documented as outputting three fields (and it
288 does), but when read it appears as two fields (array elements). This
289 is caused by the lack of whitespace between the second and third field.
290 So this function gropes the md5sum output and returns:
           32 character checksum in hexidecimal (UCFS filename)
291
      [0]
              Single character: ' 'text file, '*' binary file
       [1]
            Filesystem (20th Century Style) name
293
      [2]
294
      Note: That name may be the character '-' indicating STDIN read.

Mariusz Gniazdowski contributes a hash library for use in scripts.

Example A-22. Library of hash functions

```
1 # Hash:
 2 # Hash function library
 3 # Author: Mariusz Gniazdowski <mgniazd-at-gmail.com>
 4 # Date: 2005-04-07
 6 # Functions making emulating hashes in Bash a little less painful.
 7
 8
 9 #
      Limitations:
10 # * Only global variables are supported.
11 # * Each hash instance generates one global variable per value.
12 # * Variable names collisions are possible
13 #+ if you define variable like __hash__hashname_key
14 # * Keys must use chars that can be part of a Bash variable name
15 #+ (no dashes, periods, etc.).
16 # * The hash is created as a variable:
17 #
       ... hashname_keyname
      So if somone will create hashes like:
18 #
       myhash_ + mykey = myhash__mykey
19 #
20 #
         myhash + _mykey = myhash__mykey
21 #
      Then there will be a collision.
       (This should not pose a major problem.)
2.4
25 Hash_config_varname_prefix=__hash__
27
28 # Emulates: hash[key]=value
29 #
30 # Params:
31 # 1 - hash
32 # 2 - key
33 # 3 - value
34 function hash_set {
35
     eval "${Hash_config_varname_prefix}${1}_${2}=\"${3}\""
36 }
37
38
39 # Emulates: value=hash[key]
40 #
41 # Params:
42 # 1 - hash
43 # 2 - key
44 # 3 - value (name of global variable to set)
45 function hash_get_into {
     eval "$3=\"\$${Hash_config_varname_prefix}${1}_${2}\""
46
47 }
```

```
48
 49
 50 # Emulates: echo hash[key]
 51 #
 52 # Params:
 53 # 1 - hash
 54 # 2 - key
 55 \# 3 - echo params (like -n, for example)
 56 function hash_echo {
       eval "echo $3 \"\$${Hash_config_varname_prefix}${1}_${2}\""
 58 }
 59
 60
 61 # Emulates: hash1[key1]=hash2[key2]
 62 #
 63 # Params:
 64 # 1 - hash1
 65 # 2 - key1
 66 # 3 - hash2
 67 # 4 - key2
 68 function hash_copy {
 69 eval "${Hash_config_varname_prefix}${1}_${2}\
 70 =\"\${Hash_config_varname_prefix}${3}_${4}\""
 71 }
 72
 73
 74 # Emulates: hash[keyN-1]=hash[key2]=...hash[key1]
 76 # Copies first key to rest of keys.
 77 #
 78 # Params:
 79 # 1 - hash1
 80 # 2 - key1
 81 # 3 - key2
 82 # . . .
 83 # N - keyN
 84 function hash_dup {
     local hashName="$1" keyName="$2"
     shift 2
 87
    until [ ${#} -le 0 ]; do
      eval "${Hash_config_varname_prefix}${hashName}_${1}\
 89 =\"\$${Hash_config_varname_prefix}${hashName}_${keyName}\""
 90 shift;
 91 done;
 92 }
 93
 94
 95 # Emulates: unset hash[key]
 96 #
 97 # Params:
 98 # 1 - hash
99 # 2 - key
100 function hash_unset {
       eval "unset ${Hash_config_varname_prefix}${1}_${2}"
101
102 }
103
104
105 # Emulates something similar to: ref=&hash[key]
106 #
107 # The reference is name of the variable in which value is held.
108 #
109 # Params:
110 # 1 - hash
111 # 2 - key
112 # 3 - ref - Name of global variable to set.
113 function hash_get_ref_into {
```

```
114
      eval "$3=\"${Hash_config_varname_prefix}${1}_${2}\""
115 }
116
117
118 # Emulates something similar to: echo &hash[key]
120 # That reference is name of variable in which value is held.
121 #
122 # Params:
123 # 1 - hash
124 # 2 - key
125 # 3 - echo params (like -n for example)
126 function hash_echo_ref {
      eval "echo $3 \"${Hash_config_varname_prefix}${1}_${2}\""
128 }
129
130
131
132 # Emulates something similar to: $$hash[key](param1, param2, ...)
133 #
134 # Params:
135 # 1 - hash
136 # 2 - key
137 # 3,4, ... - Function parameters
138 function hash_call {
139 local hash key
140 hash=$1
141 key=$2
142 shift 2
eval "eval \"\${Hash\_config\_varname\_prefix}{hash}_${key} \\\"\\$@\\\"\""
144 }
145
146
147 # Emulates something similar to: isset(hash[key]) or hash[key] == NULL
148 #
149 # Params:
150 # 1 - hash
151 # 2 - key
152 # Returns:
153 \# 0 - there is such key
154 # 1 - there is no such key
155 function hash_is_set {
156 eval "if [[ \"\${{\text{hash\_config\_varname\_prefix}}}{1}_${2}-a}\" = \"a\" &&
157 \"\${${Hash_config_varname_prefix}${1}_${2}-b}\" = \"b\" ]]
158
      then return 1; else return 0; fi"
159 }
160
161
162 # Emulates something similar to:
163 # foreach($hash as $key => $value) { fun($key,$value); }
165 # It is possible to write different variations of this function.
166 # Here we use a function call to make it as "generic" as possible.
167 #
168 # Params:
169 # 1 - hash
170 # 2 - function name
171 function hash_foreach {
172
    local keyname oldIFS="$IFS"
173
     IFS=' '
174
     for i in $(eval "echo \${!${Hash_config_varname_prefix}${1}_*}"); do
175

176
177
     done
178 IFS="$oldIFS"
179 }
```

```
180
181 # NOTE: In lines 103 and 116, ampersand changed.
182 # But, it doesn't matter, because these are comment lines anyhow.
```

Here is an example script using the foregoing hash library.

Example A-23. Colorizing text using hash functions

```
1 #!/bin/bash
 2 # hash-example.sh: Colorizing text.
 3 # Author: Mariusz Gniazdowski <mgniazd-at-gmail.com>
 5 . Hash.lib
               # Load the library of functions.
7 hash_set colors red
                                "\033[0;31m"
8 hash_set colors blue
                               "\033[0;34m"
9 hash_set colors light_blue "\033[1;34m"
10 hash_set colors light_red
                                "\033[1;31m"
                                "\033[0;36m"
11 hash_set colors cyan
12 hash_set colors light_green "\033[1;32m"
13 hash_set colors light_gray "\033[0;37m"
14 hash_set colors green "\033[0;32m" 15 hash_set colors yellow "\033[1;33m"
                               "\033[0;32m"
16 hash_set colors light_purple "\033[1;35m"
17 hash_set colors purple "\033[0;35m"
18 hash_set colors reset_color "\033[0;00m"
19
20
21 # $1 - keyname
22 # $2 - value
23 try_colors() {
   echo -en "$2"
24
     echo "This line is $1."
2.5
26 }
27 hash_foreach colors try_colors
28 hash_echo colors reset_color -en
30 echo -e '\nLet us overwrite some colors with yellow.\n'
31 # It's hard to read yellow text on some terminals.
32 hash_dup colors yellow red light_green blue green light_gray cyan
33 hash_foreach colors try_colors
34 hash_echo colors reset_color -en
35
36 echo -e '\nLet us delete them and try colors once more . . .\n'
38 for i in red light_green blue green light_gray cyan; do
39 hash_unset colors $i
41 hash_foreach colors try_colors
42 hash_echo colors reset_color -en
43
44 hash_set other txt "Other examples . . ."
45 hash_echo other txt
46 hash_get_into other txt text
47 echo $text
48
49 hash_set other my_fun try_colors
50 hash_call other my_fun purple "`hash_echo colors purple`"
51 hash_echo colors reset_color -en
53 echo; echo "Back to normal?"; echo
54
55 exit $?
```

```
56
57 # On some terminals, the "light" colors print in bold,
58 # and end up looking darker than the normal ones.
59 # Why is this?
60
```

An example illustrating the mechanics of hashing, but from a different point of view.

Example A-24. More on hash functions

```
1 #!/bin/bash
 2 # $Id: ha.sh,v 1.2 2005/04/21 23:24:26 oliver Exp $

140
141 # Exercise:
142 # -----
143
144 # Add error checks to the functions.
```

Now for a script that installs and mounts those cute USB keychain solid-state "hard drives."

Example A-25. Mounting USB keychain storage devices

```
1 #!/bin/bash
 2 # ==> usb.sh
 3 # ==> Script for mounting and installing pen/keychain USB storage devices.
 4 # ==> Runs as root at system startup (see below).
 6 # ==> Newer Linux distros (2004 or later) autodetect
 7 # ==> and install USB pen drives, and therefore don't need this script.
 8 # ==> But, it's still instructive.
10 # This code is free software covered by GNU GPL license version 2 or above.
11 # Please refer to http://www.gnu.org/ for the full license text.
13 # Some code lifted from usb-mount by Michael Hamilton's usb-mount (LGPL)
14 #+ see http://users.actrix.co.nz/michael/usbmount.html
15 #
16 # INSTALL
17 # -----
18 # Put this in /etc/hotplug/usb/diskonkey.
19 # Then look in /etc/hotplug/usb.distmap, and copy all usb-storage entries
20 #+ into /etc/hotplug/usb.usermap, substituting "usb-storage" for "diskonkey".
21 # Otherwise this code is only run during the kernel module invocation/removal
22 #+ (at least in my tests), which defeats the purpose.
23 #
24 # TODO
25 #
26 # Handle more than one diskonkey device at one time (e.g. /dev/diskonkey1
27 #+ and /mnt/diskonkey1), etc. The biggest problem here is the handling in
28 #+ devlabel, which I haven't yet tried.
29 #
30 # AUTHOR and SUPPORT
31 #

```

A script that converts a text file to HTML format.

Example A-26. Converting to HTML

```
1 #!/bin/bash
2 # tohtml.sh
3
4 # Convert a text file to HTML format.
5 # Author: Mendel Cooper
6 # License: GPL3
7 # Usage: sh tohtml.sh < textfile > htmlfile
8 # Script can easily be modified to accept source and target filenames.
9
10 # Assumptions:
11 # 1) Paragraphs in (target) text file are separated by a blank line.
12 # 2) Jpeg images (*.jpg) are located in "images" subdirectory.
13 # In the target file, the image names are enclosed in square brackets,
14 # for example, [image01.jpg].
15 # 3) Emphasized (italic) phrases begin with a space+underscore
```

```
16 #+ or the first character on the line is an underscore,
17 #+ and end with an underscore+space or underscore+end-of-line.
18

140 #+ in phrases to be italicized.
```

Here is something to warm the hearts of webmasters and mistresses everywhere: a script that saves weblogs.

```
1 #!/bin/bash
2 # archiveweblogs.sh v1.0
4 # Troy Engel <tengel@fluid.com>
5 # Slightly modified by document author.
 6 # Used with permission.
7 #
8 # This script will preserve the normally rotated and
 9 #+ thrown away weblogs from a default RedHat/Apache installation.
10 # It will save the files with a date/time stamp in the filename,
11 #+ bzipped, to a given directory.
12 #
13 # Run this from crontab nightly at an off hour,
14 #+ as bzip2 can suck up some serious CPU on huge logs:
15 # 0 2 * * * /opt/sbin/archiveweblogs.sh
17
18 PROBLEM=66
19
20 # Set this to your backup dir.
21 BKP_DIR=/opt/backups/weblogs
22
23 # Default Apache/RedHat stuff
24 LOG_DAYS="4 3 2 1"
25 LOG_DIR=/var/log/httpd
26 LOG_FILES="access_log error_log"
28 # Default RedHat program locations
29 LS=/bin/ls
30 MV=/bin/mv
31 ID=/usr/bin/id
32 CUT=/bin/cut
33 COL=/usr/bin/column
34 BZ2=/usr/bin/bzip2
35
36 # Are we root?
37 USER=`$ID -u`

Example A-28. Protecting literal strings

```
1 #! /bin/bash
 2 # protect_literal.sh
 3
4 # set -vx
 5
 6 :<<-'_Protect_Literal_String_Doc'
 7
      Copyright (c) Michael S. Zick, 2003; All Rights Reserved
 8
 9
      License: Unrestricted reuse in any form, for any purpose.
10
      Warranty: None
11
     Revision: $ID$
12
13 Documentation redirected to the Bash no-operation.
     Bash will '/dev/null' this block when the script is first read.
14
15
     (Uncomment the above set command to see this action.)
16
     Remove the first (Sha-Bang) line when sourcing this as a library
17
      procedure. Also comment out the example use code in the two
18
19
      places where shown.
20
21
22
      Usage:
          _protect_literal_str 'Whatever string meets your ${fancy}'
23
24
          Just echos the argument to standard out, hard quotes
25
          restored.
2.6
2.7
          $(_protect_literal_str 'Whatever string meets your ${fancy}')
2.8
          as the right-hand-side of an assignment statement.
29
30
31
          As the right-hand-side of an assignment, preserves the
32
          hard quotes protecting the contents of the literal during
33
           assignment.
34
35
     Notes:
36
          The strange names (\_*) are used to avoid trampling on
37
          the user's chosen names when this is sourced as a
38
          library.
39
40 _Protect_Literal_String_Doc
41
42 # The 'for illustration' function form
43
44 _protect_literal_str() {
46 # Pick an un-used, non-printing character as local IFS.
47 # Not required, but shows that we are ignoring it.
48
     local IFS=$'\x1B'
                                      # \ESC character
49
50 \# Enclose the All-Elements-Of in hard quotes during assignment.
51
     local tmp=$'\x27'$@$'\x27'
52 # local tmp=$'\''$@$'\''
                                     # Even uglier.
53
     local len=${#tmp}
                                      # Info only.

55
       echo $tmp is $len long.
                                    # Output AND information.
56 }
57
58 # This is the short-named version.
```

```
59 _pls() {
 local IFS=$'x1B'
                                        # \ESC character (not required)
      echo $'\x27'$@$'\x27'
 61
                                        # Hard quoted parameter glob
 62 }
 64 # :<<-'_Protect_Literal_String_Test'
 65 # # Remove the above "# " to disable this code. # # #
 67 # See how that looks when printed.
 68 echo
 69 echo "- - Test One - -"
 70 _protect_literal_str 'Hello $user'
 71 _protect_literal_str 'Hello "${username}"'
 72 echo
 73
 74 # Which yields:
 75 # - - Test One -
 76 # 'Hello $user' is 13 long.
 77 # 'Hello "${username}"' is 21 long.
 79 # Looks as expected, but why all of the trouble?
 80 \# The difference is hidden inside the Bash internal order
 81 #+ of operations.
 82 # Which shows when you use it on the RHS of an assignment.
 83
 84 # Declare an array for test values.
 85 declare -a arrayZ
 87 # Assign elements with various types of quotes and escapes.
 88 arrayZ=( zero "$(_pls 'Hello ${Me}')" 'Hello ${You}' "\'Pass: pw\'" )
 90 # Now list that array and see what is there.
 91 echo "- - Test Two - -"
 92 for (( i=0 ; i<${#arrayZ[*]} ; i++ ))
       echo Element $i: ${arrayZ[$i]} is: ${#arrayZ[$i]} long.
 95 done
 96 echo
 97
 98 # Which yields:
 99 # - - Test Two - -
100 # Element 0: zero is: 4 long.
                                    # Our marker element
101 # Element 1: 'Hello ${Me}' is: 13 long. # Our "$(_pls '...')"
102 # Element 2: Hello ${You} is: 12 long. # Quotes are missing
103 # Element 3: \'Pass: \' is: 10 long.
                                           # ${pw} expanded to nothing
104
105 # Now make an assignment with that result.
106 declare -a array2=( ${arrayZ[@]})
108 # And print what happened.
109 echo "- - Test Three - -"
110 for (( i=0 ; i<${#array2[*]} ; i++ ))
111 do
112 echo Element $i: ${array2[$i]} is: ${#array2[$i]} long.
113 done
114 echo
115
116 # Which yields:
117 # - - Test Three - -
118 # Element 0: zero is: 4 long.
                                    # Our marker element.
119 # Element 1: Hello ${Me} is: 11 long. # Intended result.
120 # Element 2: Hello is: 5 long. # ${You} expanded to nothing.
121 # Element 3: 'Pass: is: 6 long. # Split on the whitespace.
122 # Element 4: ' is: 1 long.
                                            # The end quote is here now.
123
124 # Our Element 1 has had its leading and trailing hard quotes stripped.
```

```
125 # Although not shown, leading and trailing whitespace is also stripped.
126 # Now that the string contents are set, Bash will always, internally,
127 #+ hard quote the contents as required during its operations.
128
129 # Why?
130 # Considering our "$(_pls 'Hello ${Me}')" construction:
131 # " ... " -> Expansion required, strip the quotes.
132 # $( ... ) -> Replace with the result of..., strip this.
133 \# _pls ' ... ' -> called with literal arguments, strip the quotes.
134 # The result returned includes hard quotes; BUT the above processing
135 #+ has already been done, so they become part of the value assigned.
137 # Similarly, during further usage of the string variable, the ${Me}
138 #+ is part of the contents (result) and survives any operations
139 # (Until explicitly told to evaluate the string).
141 # Hint: See what happens when the hard quotes ($'\x27') are replaced
142 \#+ with soft quotes (\$'\x22') in the above procedures.
143 # Interesting also is to remove the addition of any quoting.
144
145 # _Protect_Literal_String_Test
146 # # # Remove the above "# " to disable this code. # # #
147
148 exit 0
```

What if you want the shell to expand and reinterpret strings?

Example A-29. Unprotecting literal strings

```
1 #! /bin/bash
 2 # unprotect_literal.sh
 4 # set -vx
 6 :<<-'_UnProtect_Literal_String_Doc'
       Copyright (c) Michael S. Zick, 2003; All Rights Reserved
 8
 9
      License: Unrestricted reuse in any form, for any purpose.
10
      Warranty: None
      Revision: $ID$
11
12
13
      Documentation redirected to the Bash no-operation. Bash will
      '/dev/null' this block when the script is first read.
14
15
       (Uncomment the above set command to see this action.)
16
17
      Remove the first (Sha-Bang) line when sourcing this as a library
18
       procedure. Also comment out the example use code in the two
19
      places where shown.
20
21
22
       Usage:
23
           Complement of the "$(_pls 'Literal String')" function.
24
           (See the protect_literal.sh example.)
25
26
           StringVar=$(_upls ProtectedSringVariable)
27
28
      Does:
29
           When used on the right-hand-side of an assignment statement;
30
           makes the substitions embedded in the protected string.
31
32
      Notes:
33
           The strange names (_*) are used to avoid trampling on
34
           the user's chosen names when this is sourced as a

84 echo $newVar
86 # Do we really need a function to do this?
87 newerVar=$(eval echo ${array2[1]})
88 echo $newerVar
90 # I guess not, but the _upls function gives us a place to hang
91 #+ the documentation on.
92 # This helps when we forget what a # construction like:
93 #+ $(eval echo ...) means.
94
95 # What if Me isn't set when the protected string is evaluated?
96 unset Me
97 newestVar=$(_upls ${array2[1]})
98 echo $newestVar
99
100 # Just gone, no hints, no runs, no errors.
```

```
101
102 # Why in the world?
103 # Setting the contents of a string variable containing character
104 #+ sequences that have a meaning in Bash is a general problem in
105 #+ script programming.
107 # This problem is now solved in eight lines of code
108 #+ (and four pages of description).
109
110 # Where is all this going?
111 # Dynamic content Web pages as an array of Bash strings.
112 # Content set per request by a Bash 'eval' command
113 #+ on the stored page template.
114 # Not intended to replace PHP, just an interesting thing to do.
115 ###
116 # Don't have a webserver application?
117 # No problem, check the example directory of the Bash source;
118 #+ there is a Bash script for that also.
119
120 # _UnProtect_Literal_String_Test
121 # # # Remove the above "# " to disable this code. # # #

This powerful script helps hunt down spammers.

Example A-30. Spammer Identification

```
1 #!/bin/bash
 3 # $Id: is_spammer.bash,v 1.12.2.11 2004/10/01 21:42:33 mszick Exp $
 4 # Above line is RCS info.
 6 # The latest version of this script is available from http://www.morethan.org.
7 #
 8 # Spammer-identification
9 # by Michael S. Zick
10 # Used in the ABS Guide with permission.
11
12
13
14 ##############
15 # Documentation
16 # See also "Quickstart" at end of script.
19 :<<-'__is_spammer_Doc_'

2.4
25 Impatient?
      Application code: goto "# # # Hunt the Spammer' program code # # #"
26
27
      Example output: ":<<-'_is_spammer_outputs_'"</pre>
28
      How to use: Enter script name without arguments.
29
                  Or goto "Quickstart" at end of script.
30
31 Provides
32
      Given a domain name or IP(v4) address as input:
33
34
      Does an exhaustive set of queries to find the associated
```

```
35
       network resources (short of recursing into TLDs).
36
37
       Checks the IP(v4) addresses found against Blacklist
38
       nameservers.
39
       If found to be a blacklisted IP(v4) address,
40
41
       reports the blacklist text records.
42
        (Usually hyper-links to the specific report.)
43
44 Requires
4.5
       A working Internet connection.
46
        (Exercise: Add check and/or abort if not on-line when running script.)
        Bash with arrays (2.05b+).
47
48
49
       The external program 'dig' --
50
       a utility program provided with the 'bind' set of programs.
51
       Specifically, the version which is part of Bind series 9.x
52
       See: http://www.isc.org
53
54
       All usages of 'dig' are limited to wrapper functions,
5.5
       which may be rewritten as required.
56
       See: dig_wrappers.bash for details.
57
             ("Additional documentation" -- below)
58
59 Usage
60
       Script requires a single argument, which may be:
61
       1) A domain name;
62
       2) An IP(v4) address;
63
       3) A filename, with one name or address per line.
64
65
       Script accepts an optional second argument, which may be:
       1) A Blacklist server name;
66
67
       2) A filename, with one Blacklist server name per line.
68
69
       If the second argument is not provided, the script uses
70
       a built-in set of (free) Blacklist servers.
71
72
       See also, the Quickstart at the end of this script (after 'exit').
73
74 Return Codes
75
       0 - All OK
76
       1 - Script failure
77
       2 - Something is Blacklisted
78
79 Optional environment variables
80 SPAMMER_TRACE
81
           If set to a writable file,
82
           script will log an execution flow trace.
83
84
       SPAMMER_DATA
85
           If set to a writable file, script will dump its
            discovered data in the form of GraphViz file.
86
87
           See: http://www.research.att.com/sw/tools/graphviz
88
89
        SPAMMER_LIMIT
90
           Limits the depth of resource tracing.
91
92
           Default is 2 levels.
93
94
           A setting of 0 (zero) means 'unlimited' . . .
95
             Caution: script might recurse the whole Internet!
96
97
           A limit of 1 or 2 is most useful when processing
98
           a file of domain names and addresses.
99
           A higher limit can be useful when hunting spam gangs.
100
```

```

106
107
108 Study notes
109
       This script uses a large number of functions.
       Nearly all general functions have their own example script.
110
111
       Each of the example scripts have tutorial level comments.
112
113 Scripting project
114
       Add support for IP(v6) addresses.
115
       IP (v6) addresses are recognized but not processed.
116
117 Advanced project
118
       Add the reverse lookup detail to the discovered information.
119
120
       Report the delegation chain and abuse contacts.
121
122
       Modify the GraphViz file output to include the
123
      newly discovered information.

1566 # (See also, "Quickstart" at end of script.)
1567 usage() {
      cat <<-'_usage_statement_'
1568
1569
        The script is_spammer.bash requires either one or two arguments.
1570
1571
       arg 1) May be one of:
1572
            a) A domain name
1573
            b) An IPv4 address
1574
            c) The name of a file with any mix of names
1575
               and addresses, one per line.
1576
1577
       arg 2) May be one of:
1578
            a) A Blacklist server domain name
1579
            b) The name of a file with Blacklist server
1580
               domain names, one per line.
1581
            c) If not present, a default list of (free)
1582
               Blacklist servers is used.
1583
            d) If a filename of an empty, readable, file
1584
               is given,
1585
               Blacklist server lookup is disabled.
1586
1587
        All script output is written to stdout.
1588
        Return codes: 0 -> All OK, 1 -> Script failure,
1589
1590
                      2 -> Something is Blacklisted.
1591
1592
       Requires the external program 'dig' from the 'bind-9'
1593
        set of DNS programs. See: http://www.isc.org
1594
1595
       The domain name lookup depth limit defaults to 2 levels.
1596
        Set the environment variable SPAMMER_LIMIT to change.
1597
        SPAMMER_LIMIT=0 means 'unlimited'
1598
1599
       Limit may also be set on the command line.
1600
       If arg#1 is an integer, the limit is set to that value
1601
        and then the above argument rules are applied.
1602
       Setting the environment variable 'SPAMMER_DATA' to a filename
1603
1604
       will cause the script to write a GraphViz graphic file.
1605
1606
       For the development version;
       Setting the environment variable 'SPAMMER_TRACE' to a filename
1607
1608
        will cause the execution engine to log a function call trace.
1609

1900 Advanced Bash Scripting Guide: is_spammer.bash, v2, 2004-msz
1901
1902 _is_spammer_outputs_
1903
1904 exit ${_hs_RC}
1905
1907 # The script ignores everything from here on down #
1908 #+ because of the 'exit' command, just above.
1910
1911
1912
1913 Quickstart
1914 ======
1915
1916 Prerequisites
1917
1918
     Bash version 2.05b or 3.00 (bash --version)
1919
      A version of Bash which supports arrays. Array
1920
      support is included by default Bash configurations.
1921
1922
      'dig,' version 9.x.x (dig $HOSTNAME, see first line of output)
1923
     A version of dig which supports the +short options.
1924
     See: dig_wrappers.bash for details.
1925
1926
1927 Optional Prerequisites
1928
1929 'named,' a local DNS caching program. Any flavor will do.
1930 Do twice: dig $HOSTNAME
1931 Check near bottom of output for: SERVER: 127.0.0.1#53
1932 That means you have one running.
1933
1934
1935 Optional Graphics Support
1936
1937
      'date,' a standard *nix thing. (date -R)
1938
1939
      dot Program to convert graphic description file to a
1940
      diagram. (dot -V)
1941
      A part of the Graph-Viz set of programs.
1942
      See: [http://www.research.att.com/sw/tools/graphviz||GraphViz]
1943
1944
      'dotty,' a visual editor for graphic description files.
      Also a part of the Graph-Viz set of programs.
1945
1946
1947
1948
```

```
1949
1950 Quick Start
1952 In the same directory as the is_spammer.bash script;
1953 Do: ./is_spammer.bash
1955 Usage Details
1956
1957 1. Blacklist server choices.
1958
1959
       (a) To use default, built-in list: Do nothing.
1960
1961
      (b) To use your own list:
1962
1963
       i. Create a file with a single Blacklist server
1964
           domain name per line.
1965
1966
       ii. Provide that filename as the last argument to
1967
            the script.
1968
1969
      (c) To use a single Blacklist server: Last argument
1970
          to the script.
1971
1972
     (d) To disable Blacklist lookups:
1973
1974
       i. Create an empty file (touch spammer.nul)
1975
           Your choice of filename.
1976
       ii. Provide the filename of that empty file as the
1977
1978
            last argument to the script.
1979
1980 2. Search depth limit.
1981
1982
      (a) To use the default value of 2: Do nothing.
1983
1984
     (b) To set a different limit:
1985
         A limit of 0 means: no limit.
1986
       i. export SPAMMER_LIMIT=1
1987
1988
          or whatever limit you want.
1989
1990 ii. OR provide the desired limit as the first
1991
          argument to the script.
1992
1993 3. Optional execution trace log.
1994
1995
     (a) To use the default setting of no log output: Do nothing.
1996
1997 (b) To write an execution trace log:
1998
          export SPAMMER_TRACE=spammer.log
1999
          or whatever filename you want.
2000
2001 4. Optional graphic description file.
2002
2003
       (a) To use the default setting of no graphic file: Do nothing.
2004
2005
       (b) To write a Graph-Viz graphic description file:
2006
          export SPAMMER_DATA=spammer.dot
2007
          or whatever filename you want.
2008
2009 5. Where to start the search.
2010
2011
      (a) Starting with a single domain name:
2012
2013
       i. Without a command line search limit: First
2014
           argument to script.
```

```
2015
2016
        ii. With a command line search limit: Second
2017
             argument to script.
2018
2019
       (b) Starting with a single IP address:
2020
2021
         i. Without a command line search limit: First
2022
            argument to script.
2023
2024
         ii. With a command line search limit: Second
2025
             argument to script.
2026
       (c) Starting with (mixed) multiple name(s) and/or address(es):
2027
2028
           Create a file with one name or address per line.
2029
           Your choice of filename.
2030
2031
         i. Without a command line search limit: Filename as
2032
            first argument to script.
2033
2034
         ii. With a command line search limit: Filename as
2035
             second argument to script.
2036
2037 6. What to do with the display output.
2038
2039
       (a) To view display output on screen: Do nothing.
2040
       (b) To save display output to a file: Redirect stdout to a filename.
2.041
2.042
       (c) To discard display output: Redirect stdout to /dev/null.
2043
2044
2045 7. Temporary end of decision making.
2046
        press RETURN
2047
        wait (optionally, watch the dots and colons).
2048
2049 8. Optionally check the return code.
2050
2051
       (a) Return code 0: All OK
2052
2053
      (b) Return code 1: Script setup failure
2054
2055
      (c) Return code 2: Something was blacklisted.
2056
2057 9. Where is my graph (diagram)?
2058
2059 The script does not directly produce a graph (diagram).
2060 It only produces a graphic description file. You can
2061 process the graphic descriptor file that was output
2062 with the 'dot' program.
2064 Until you edit that descriptor file, to describe the
2065 relationships you want shown, all that you will get is
2066 a bunch of labeled name and address nodes.
2067
2068 All of the script's discovered relationships are within
2069 a comment block in the graphic descriptor file, each
2070 with a descriptive heading.
2072 The editing required to draw a line between a pair of
2073 nodes from the information in the descriptor file may
2074 be done with a text editor.
2075
2076 Given these lines somewhere in the descriptor file:
2077
2078 # Known domain name nodes
2079
2080 N0000 [label="guardproof.info."];
```

```
2081
2082 N0002 [label="third.guardproof.info."];
2083
2084
2085
2086 # Known address nodes
2087
2088 A0000 [label="61.141.32.197"] ;
2089
2090
2091
2092 /*
2093
2094 # Known name->address edges
2096 NA0000 third.guardproof.info. 61.141.32.197
2097
2098
2099
2100 # Known parent->child edges
2101
2102 PC0000 guardproof.info. third.guardproof.info.
2103
2104 */
2105
2106 Turn that into the following lines by substituting node
2107 identifiers into the relationships:
2108
2109 # Known domain name nodes
2110
2111 N0000 [label="guardproof.info."];
2112
2113 N0002 [label="third.guardproof.info."];
2114
2115
2116
2117 # Known address nodes
2118
2119 A0000 [label="61.141.32.197"];
2120
2121
2122
2123 # PC0000 quardproof.info. third.quardproof.info.
2124

2148
2149 Process that with the 'dot' program, and you have your
2150 first network diagram.
2152 In addition to the conventional graphic edges, the
2153 descriptor file includes similar format pair-data that
2154 describes services, zone records (sub-graphs?),
2155 blacklisted addresses, and other things which might be
2156 interesting to include in your graph. This additional
2157 information could be displayed as different node
2158 shapes, colors, line sizes, etc.
2159
2160 The descriptor file can also be read and edited by a
2161 Bash script (of course). You should be able to find
2162 most of the functions required within the
2163 "is_spammer.bash" script.
2164
2165 # End Quickstart.
2166
2167
2168
2169 Additional Note
2170 ======= ====
2171
2172 Michael Zick points out that there is a "makeviz.bash" interactive
2173 Web site at rediris.es. Can't give the full URL, since this is not
2174 a publically accessible site.
```

Another anti-spam script.

Example A-31. Spammer Hunt

```
1 #!/bin/bash
2 # whx.sh: "whois" spammer lookup
3 # Author: Walter Dnes
 4 # Slight revisions (first section) by ABS Guide author.
5 # Used in ABS Guide with permission.
7 \# Needs version 3.x or greater of Bash to run (because of =~ operator).
8 # Commented by script author and ABS Guide author.

271 #@ ABS Guide author comments:
272 #@ Nothing fancy here, but still a very useful tool for hunting spammers.
273 #@ Sure, the script can be cleaned up some, and it's still a bit buggy,
274 #@+ (exercise for reader), but all the same, it's a nice piece of coding
275 #@+ by Walter Dnes.
276 #@ Thank you!
```

"Little Monster's" front end to wget.

Example A-32. Making wget easier to use

```
1 #!/bin/bash
2 # wgetter2.bash
3
4 # Author: Little Monster [monster@monstruum.co.uk]
5 # ==> Used in ABS Guide with permission of script author.
6 # ==> This script still needs debugging and fixups (exercise for reader).
7 # ==> It could also use some additional editing in the comments.
8
9
```

```
10 # This is wgetter2 --
11 #+ a Bash script to make wget a bit more friendly, and save typing.
13 # Carefully crafted by Little Monster.
14 \# More or less complete on 02/02/2005.
15 # If you think this script can be improved,
16 #+ email me at: monster@monstruum.co.uk
17 # ==> and cc: to the author of the ABS Guide, please.
18 # This script is licenced under the GPL.
19 # You are free to copy, alter and re-use it,
20 #+ but please don't try to claim you wrote it.
21 # Log your changes here instead.
2.2.
24 # changelog:
26 \# 07/02/2005. Fixups by Little Monster.
27 \ \# \ 02/02/2005. Minor additions by Little Monster.
               (See after # ++++++++ )
28 #
29 \# 29/01/2005. Minor stylistic edits and cleanups by author of ABS Guide.
30 #
               Added exit error codes.
31 \# 22/11/2004. Finished initial version of second version of wgetter:
               wgetter2 is born.
32 #
33 \# 01/12/2004. Changed 'runn' function so it can be run 2 ways --
34 #
                either ask for a file name or have one input on the CL.
35 \# 01/12/2004. Made sensible handling of no URL's given.
36 # 01/12/2004. Made loop of main options, so you don't
               have to keep calling wgetter 2 all the time.
38 #
               Runs as a session instead.
39 # 01/12/2004. Added looping to 'runn' function.
                Simplified and improved.
41 # 01/12/2004. Added state to recursion setting.
                Enables re-use of previous value.
43 \ \# \ 05/12/2004. Modified the file detection routine in the 'runn' function
                so it's not fooled by empty values, and is cleaner.
45 # 01/02/2004. Added cookie finding routine from later version (which
46 # isn't ready yet), so as not to have hard-coded paths.
47 # -----

11
12 # ==> ABS Guide extra comments.
13
14 # ==> Author of this script has kindly granted permission
15 # ==>+ for inclusion in ABS Guide.
16
17
18 # ==> ######################
19 #
20 # ==> What is "podcasting"?
22 # ==> It's broadcasting "radio shows" over the Internet.
23 \# ==> These shows can be played on iPods and other music file players.
25 # ==> This script makes it possible.
26 # ==> See documentation at the script author's site, above.
2.7
29
30
31 # Make script crontab friendly:
32 cd $(dirname $0)
33 # ==> Change to directory where this script lives.
35 # datadir is the directory you want podcasts saved to:
36 datadir=$(date +%Y-%m-%d)
37 # ==> Will create a directory with the name: YYYY-MM-DD
39 # Check for and create datadir if necessary:
40 if test ! -d $datadir
41
         then
42
         mkdir $datadir
43 fi
44
45 # Delete any temp file:
```

```
46 rm -f temp.log
47
48 # Read the bp.conf file and wget any url not already in the podcast.log file:
49 while read podcast
50 do # ==> Main action follows.
51 file=$(wget -q $podcast -0 - | tr '\r' '\n' | tr \' \" | \
52 sed -n 's/.*url="\([^"]*\)".*/\1/p')
53
   for url in $file

                  done
61
      done < bp.conf
62
63 # Move dynamically created log file to permanent log file:
64 cat podcast.log >> temp.log
65 sort temp.log | uniq > podcast.log
66 rm temp.log
67 # Create an m3u playlist:
68 ls $datadir | grep -v m3u > $datadir/podcast.m3u
69
70
71 exit 0
72.
74 For a different scripting approach to Podcasting,
75 see Phil Salkie's article,
76 "Internet Radio to Podcast with Shell Tools"
77 in the September, 2005 issue of LINUX JOURNAL,
78 http://www.linuxjournal.com/article/8171
```

Example A-34. Nightly backup to a firewire HD

```
1 #!/bin/bash
2 # nightly-backup.sh
 3 # http://www.richardneill.org/source.php#nightly-backup-rsync
 5 # This is Free Software licensed under the GNU GPL.
 6 # ==> Included in ABS Guide with script author's kind permission.
 7 \# ==> (Thanks!)
 9 # This does a backup from the host computer to a locally connected
10 #+ firewire HDD using rsync and ssh.
11 # It then rotates the backups.
12 # Run it via cron every night at 5am.
13 # This only backs up the home directory.
14 # If ownerships (other than the user's) should be preserved,
15 \#+ then run the rsync process as root (and re-instate the -o).
16 # We save every day for 7 days, then every week for 4 weeks,
17 #+ then every month for 3 months.
19 # See: http://www.mikerubel.org/computers/rsync_snapshots/
20 #+ for more explanation of the theory.
21 # Save as: $HOME/bin/nightly-backup_firewire-hdd.sh
2.2
23 # Known bugs:
24 #
25 # i) Ideally, we want to exclude ~/.tmp and the browser caches.
```

```
2.6
27 # ii) If the user is sitting at the computer at 5am,
28 #+
       and files are modified while the rsync is occurring,
29 #+
        then the BACKUP_JUSTINCASE branch gets triggered.
30 #
       To some extent, this is a
        feature, but it also causes a "disk-space leak".

3 #
        cdll
4 #
       by Phil Braham
5 #
6 #
        7 #
        Latest version of this script available from
8 #
       http://freshmeat.net/projects/cd/
9 #
        10 #
11 #
        .cd_new
12 #
13 #
        An enhancement of the Unix cd command
14 #
15 #
        There are unlimited stack entries and special entries. The stack
16 #
       entries keep the last cd_maxhistory
17 #
        directories that have been used. The special entries can be
18 #
        assigned to commonly used directories.
19 #
20 #
        The special entries may be pre-assigned by setting the environment
21 #
        variables CDSn or by using the -u or -U command.
22 #
23 #
        The following is a suggestion for the .profile file:
24 #
25 #
                              # Set up the cd command
               . cdll
        alias cd='cd_new'
26 #
                              # Replace the cd command
27 #
              cd -U
                              # Upload pre-assigned entries for
28 #
                              #+ the stack and special entries
29 #
               cd -D
                              # Set non-default mode
30 #
               alias @="cd_new @" # Allow @ to be used to get history
31 #
32 #
       For help type:
33 #
34 #
               cd -h or
35 #
               cd -H
36 #

                                  and put current dir on special entry <n>*
 71
        -a<n>
                    Alternative suggested directory. See note below.
 72
        -f [<file>] File entries to <file>.
 73
        -u [<file>] Update entries from <file>.
 74
                    If no filename supplied then default file
 75
                    (${CDPath}${2:-"$CDFile"}) is used
 76
                    -F and -U are silent versions
 77
        -v
                   Print version number
 78
        -h
                    Help
                    Detailed help
 79
 80
        *The special entries (0 - 9) are held until log off, replaced by another
 81
 82
        entry or updated with the -u command
 83
 84
        Alternative suggested directories:
 8.5
        If a directory is not found then CD will suggest any
        possibilities. These are directories starting with the same letters
 86
 87
        and if any are found they are listed prefixed with -a<n>
 88
        where \langle n \rangle is a number.
 89
        It's possible to go to the directory by entering cd -a<n>
 90
       on the command line.
 91
 92
        The directory for -r < n >  or -R < n >  may be a number.
 93
        For example:
 94
            \$ cd -r3 4 Go to history entry 4 and put it on special entry 3
 95
            $ cd -R3 4 Put current dir on the special entry 3
 96
                        and go to history entry 4
 97
            $ cd -s3
                       Go to special entry 3
 98
99
      Note that commands R, r, S and s may be used without a number
100
        and refer to 0:
101
           $ cd -s Go to special entry 0
102
           $ cd -S
                       Go to special entry 0 and make special
103
                        entry 0 current dir
104
            $ cd -r 1 Go to history entry 1 and put it on special entry 0
105
                       Go to history entry 0 and put it on special entry 0
            $ cd -r
106
           if ${TEST} "$CD_MODE" = "PREV"
107
108
            then
109
                    ${PRINTF} "$cd_mnset"
110
            else
111
                    ${PRINTF} "$cd_mset"
112
            fi
113 }
114
115 cd_Hm ()
116 {
117
            cd_hm
            ${PRINTF} "%s" "
118
```

```
119
           The previous directories (0-$cd_maxhistory) are stored in the
120
           environment variables CD[0] - CD[$cd_maxhistory]
121
           Similarly the special directories SO - $cd_maxspecial are in
122
           the environment variable CDS[0] - CDS[$cd_maxspecial]
123
           and may be accessed from the command line
124
125
           The default pathname for the -f and -u commands is $CDPath
126
           The default filename for the -f and -u commands is $CDFile
127
128
           Set the following environment variables:
129
               CDL_PROMPTLEN - Set to the length of prompt you require.
130
                   Prompt string is set to the right characters of the
131
                   current directory.
132
                   If not set then prompt is left unchanged
133
               CDL_PROMPT_PRE - Set to the string to prefix the prompt.
134
                   Default is:
135
                      non-root: \"\[\ensuremath{\ }\]\" (sets colour to blue).
                      root: \"\\[\\e[01;31m\\]\" (sets colour to red).
136
137
               CDL_PROMPT_POST
                                 - Set to the string to suffix the prompt.
138
                   Default is:
139
                       non-root: \"\\[\\e[00m\\]$\"
140
                                  (resets colour and displays $).
141
                                  \"\\[\\e[00m\\]#\"
                       root:
142
                                   (resets colour and displays #).
143
               CDPath - Set the default path for the -f & -u options.
144
                       Default is home directory
145
               CDFile - Set the default filename for the -f & -u options.
146
                       Default is cdfile

491 =========
493 cdll is a replacement for cd and incorporates similar functionality to
494 the bash pushd and popd commands but is independent of them.
496 This version of cdll has been tested on Linux using Bash. It will work
497 on most Linux versions but will probably not work on other shells without
498 modification.
499
500 Introduction
501 =====
502
503 cdll allows easy moving about between directories. When changing to a new
504 directory the current one is automatically put onto a stack. By default
505 50 entries are kept, but this is configurable. Special directories can be
506 kept for easy access - by default up to 10, but this is configurable. The
507 most recent stack entries and the special entries can be easily viewed.
508
509 The directory stack and special entries can be saved to, and loaded from,
510 a file. This allows them to be set up on login, saved before logging out
511 or changed when moving project to project.
512
513 In addition, cdll provides a flexible command prompt facility that allows,
514 for example, a directory name in colour that is truncated from the left
```

```
515 if it gets too long.
516
517
518 Setting up cdll
519 ========
521 Copy cdll to either your local home directory or a central directory
522 such as /usr/bin (this will require root access).
523
524 Copy the file cdfile to your home directory. It will require read and
525 write access. This a default file that contains a directory stack and
526 special entries.
527
528 To replace the cd command you must add commands to your login script.
529 The login script is one or more of:
531
      /etc/profile
532
       ~/.bash_profile
533
      ~/.bash_login
534
      ~/.profile
535
       ~/.bashrc
536
      /etc/bash.bashrc.local
537
538 To setup your login, ~/.bashrc is recommended, for global (and root) setup
539 add the commands to /etc/bash.bashrc.local
541 To set up on login, add the command:
542 . <dir>/cdll
543 For example if cdll is in your local home directory:
      . ~/cdll
545 If in /usr/bin then:
. /usr/bin/cdll
547
548 If you want to use this instead of the buitin cd command then add:
      alias cd='cd_new'
550 We would also recommend the following commands:
    alias @='cd_new @'
552
      cd -U
      cd -D
553
554
555 If you want to use cdll's prompt facilty then add the following:
556 CDL_PROMPTLEN=nn
557 Where nn is a number described below. Initially 99 would be suitable
558 number.
559
560 Thus the script looks something like this:
562
       563
      # CD Setup
      **
564
      CDL_PROMPTLEN=21  # Allow a prompt length of up to 21 characters ./usr/bin/cdll  # Initialise cdll
565
566
      alias cd='cd_new'
567
                            # Replace the built in cd command
568
      alias @='cd_new @'
                            # Allow @ at the prompt to display history
569
      cd -U
                             # Upload directories
570
       cd -D
                             # Set default action to non-posix
571
573 The full meaning of these commands will become clear later.
575 There are a couple of caveats. If another program changes the directory
576 without calling cdll, then the directory won't be put on the stack and
577 also if the prompt facility is used then this will not be updated. Two
578 programs that can do this are pushd and popd. To update the prompt and
579 stack simply enter:
580
```

```
581
      cd .
582
583 Note that if the previous entry on the stack is the current directory
584 then the stack is not updated.
586 Usage
587 =====
588 cd [dir] [0-9] [@[s|h] [-q <dir>] [-d] [-D] [-r<n>]
    [dir|0-9] [-R<n>] [<dir>|0-9] [-s<n>]
      [-u] [-U] [-f] [-F] [-h] [-H] [-v]
590
591
592
       <dir>
                   Go to directory
593
                   Goto previous directory (0 is previous,
        0-n
594
                   1 is last but 1, etc.)
595
                   n is up to max history (default is 50)
596
                   List history and special entries (Usually available as $ @)
597
       @h
                   List history entries
598
       @s
                   List special entries
599
       -g [<dir>] Go to literal name (bypass special names)
                   This is to allow access to dirs called '0','1','-h' etc
600
601
                   Change default action - verbose. (See note)
       -d
602
       -D
                  Change default action - silent. (See note)
603
                  Go to the special entry <n>
       -s<n>
604
       -S<n>
                   Go to the special entry <n>
605
                         and replace it with the current dir
606
       -r<n> [<dir>] Go to directory <dir>
607
                                 and then put it on special entry <n>
608
       -R<n> [<dir>] Go to directory <dir>
609
                                 and put current dir on special entry <n>
610
                  Alternative suggested directory. See note below.
       -f [<file>] File entries to <file>.
611
612
       -u [<file>] Update entries from <file>.
613
                   If no filename supplied then default file (~/cdfile) is used
614
                   -F and -U are silent versions
615
       -\Lambda
                   Print version number
616
       -h
                   Help
                   Detailed help
617
       -H
618
619
620
621 Examples
622 ======
623
624 These examples assume non-default mode is set (that is, cd with no
625 parameters will go to the most recent stack directory), that aliases
626 have been set up for cd and @ as described above and that cd's prompt
627 facility is active and the prompt length is 21 characters.
628
629
       /home/phil$ @
630
       # List the entries with the @
631
      History:
       # Output of the @ command
632
633
634
       # Skipped these entries for brevity
635
       1 /home/phil/ummdev
                                         S1 /home/phil/perl
636
       # Most recent two history entries
637
       0 /home/phil/perl/eg
                                        S0 /home/phil/umm/ummdev
638
       # and two special entries are shown
639
640
       /home/phil$ cd /home/phil/utils/Cdll
641
       # Now change directories
642
       /home/phil/utils/Cdll$ @
643
       # Prompt reflects the directory.
644
       History:
       # New history
645
646
        . . . . .
```

```
647
       1 /home/phil/perl/eg
                                        S1 /home/phil/perl
648
       # History entry 0 has moved to 1
649
       0 /home/phil
                                        S0 /home/phil/umm/ummdev
650
       # and the most recent has entered
652 To go to a history entry:
653
654
       /home/phil/utils/Cdll$ cd 1
655
       # Go to history entry 1.
       /home/phil/perl/eg$
656
657
        # Current directory is now what was 1
658
659 To go to a special entry:
660
661
       /home/phil/perl/eg$ cd -s1
662
       # Go to special entry 1
663
       /home/phil/umm/ummdev$
       # Current directory is S1
664
665
666 To go to a directory called, for example, 1:
667
668
       /home/phil$ cd -q 1
669
       # -g ignores the special meaning of 1
670
       /home/phil/1$
671
672 To put current directory on the special list as S1:
673 cd-r1 . # OR
                       # These have the same effect if the directory is
674
       cd -R1 .
675
                       #+ . (the current directory)
676
677 To go to a directory and add it as a special
The directory for -r < n > or -R < n > may be a number.
679 For example:
680
           $ cd -r3 4 Go to history entry 4 and put it on special entry 3
           \ cd -R3 4 \, Put current dir on the special entry 3 and go to
681
682
                       history entry 4
                       Go to special entry 3
683
           $ cd -s3
684
685
      Note that commands R,r,S and s may be used without a number and
      refer to 0:
686
687
         $ cd -s
                      Go to special entry 0
688
           $ cd -S Go to special entry 0 and make special entry 0
689
                       current dir
690
           $ cd -r 1 Go to history entry 1 and put it on special entry 0
691
           \$ cd -r Go to history entry 0 and put it on special entry 0
692
693
694
       Alternative suggested directories:
695
      If a directory is not found, then CD will suggest any
       possibilities. These are directories starting with the same letters
697
698
       and if any are found they are listed prefixed with -a<n>
699
       where \langle n \rangle is a number. It's possible to go to the directory
700
       by entering cd -a < n > on the command line.
701
702
           Use cd -d or -D to change default cd action. cd -H will show
703
           current action.
704
705
           The history entries (0-n) are stored in the environment variables
706
           CD[0] - CD[n]
707
           Similarly the special directories SO - 9 are in the environment
708
           variable CDS[0] - CDS[9]
709
           and may be accessed from the command line, for example:
710
711
               ls -1 $\{CDS[3]\}
712
               cat ${CD[8]}/file.txt
```

```
713
714
            The default pathname for the -f and -u commands is \sim
715
            The default filename for the -f and -u commands is cdfile
716
717
718 Configuration
719 =======
720
721
       The following environment variables can be set:
722
723
            CDL_PROMPTLEN - Set to the length of prompt you require.
724
                Prompt string is set to the right characters of the current
                directory. If not set, then prompt is left unchanged. Note
725
726
                that this is the number of characters that the directory is
727
                shortened to, not the total characters in the prompt.
728
729
                CDL_PROMPT_PRE - Set to the string to prefix the prompt.
730
                    Default is:
731
                       non-root: "\[\ensuremath{\ }\]" (sets colour to blue).
                                   "\\[\\e[01;31m\\]" (sets colour to red).
732
                       root:
733
734
                CDL_PROMPT_POST
                                  - Set to the string to suffix the prompt.
735
                   Default is:
736
                       non-root: "\\[\\e[00m\\]$"
737
                                  (resets colour and displays $).
738
                                   "\\[\\e[00m\\]#"
739
                                   (resets colour and displays #).
740
741
           Note:
742
                CDL_PROMPT_PRE & _POST only t
743
744
            CDPath - Set the default path for the -f & -u options.
745
                    Default is home directory
746
            CDFile - Set the default filename for the -f & -u options.
747
                    Default is cdfile
748
749
750
       There are three variables defined in the file cdll which control the
751
        number of entries stored or displayed. They are in the section labeled
752
       'Initialisation here' towards the end of the file.
753
754
                               - The number of history entries stored.
           cd_maxhistory
755
                                 Default is 50.
756
                               - The number of special entries allowed.
           cd_maxspecial
757
                                 Default is 9.
758
           cd_histcount
                               - The number of history and special entries
759
                                 displayed. Default is 9.
760
761
      Note that cd_maxspecial should be >= cd_histcount to avoid displaying
762
        special entries that can't be set.
763

5 # http://www.thinkwiki.org/wiki ...
 6 # /Script_for_configuring_the_CS4239_sound_chip_in_PnP_mode
7 # ABS Guide author made minor changes and added comments.
8 # Couldn't contact script author to ask for permission to use, but ...
 9 #+ the script was released under the FDL,
10 #+ so its use here should be both legal and ethical.
11
12 # Sound-via-pnp-script for Thinkpad 600E
13 #+ and possibly other computers with onboard CS4239/CS4610
14 #+ that do not work with the PCI driver
15 #+ and are not recognized by the PnP code of snd-cs4236.
16 \# Also for some 770-series Thinkpads, such as the 770x.
17 # Run as root user, of course.
18 #
19 # These are old and very obsolete laptop computers,
20 #+ but this particular script is very instructive,
21 #+ as it shows how to set up and hack device files.
23
2.4
25 # Search for sound card pnp device:
27 for dev in /sys/bus/pnp/devices/*
28 do

Example A-37. Locate split paragraphs in a text file

```
1 #!/bin/bash
2 # find-splitpara.sh
3 # Finds split paragraphs in a text file,
4 #+ and tags the line numbers.
7 ARGCOUNT=1
                  # Expect one arg.
8 E_WRONGARGS=65
10 file="$1"
                 # Target filename.
11 lineno=1
                 # Line number. Start at 1.
12 Flag=0
                   # Blank line flag.
13
14 if [ $# -ne "$ARGCOUNT" ]
15 then
16 echo "Usage: `basename $0` FILENAME"
17 exit $E_WRONGARGS
18 fi
19
20 file_read ()
                 # Scan file for pattern, then print line.
22 while read line
23 do
```

```
2.4
25
   if [[ "$line" =~ ^[a-z] && $Flag -eq 1 ]]
     then # Line begins with lc character, following blank line.
26
27
      echo -n "$lineno:: "
28
      echo "$line"
29 fi
30
31
32 if [[ "$line" =~ "^$" ]]
     then # If blank line,
Flag=1 #+ set flag.
33
34
35 else
    Flag=0
36
37
    fi
38
39
   ((lineno++))
40
41 done
42 } < $file # Redirect file into function's stdin.
4.3
44 file_read
4.5
46
47 exit $?
48
49
51 This is line one of an example paragraph, bla, bla, bla.
52 This is line two, and line three should follow on next line, but
54 there is a blank line separating the two parts of the paragraph.
55 # -----
57 Running this script on a file containing the above paragraph
58 yields:
60 4:: there is a blank line separating the two parts of the paragraph.
63 There will be additional output for all the other split paragraphs
64 in the target file.
```

Example A-38. Insertion sort

```
1 #!/bin/bash
 2 # insertion-sort.bash: Insertion sort implementation in Bash
                  Heavy use of Bash array features:
                        (string) slicing, merging, etc
 5 # URL: http://www.lugmen.org.ar/~jjo/jjotip/insertion-sort.bash.d
 6 #+ /insertion-sort.bash.sh
 7 #
 8 # Author: JuanJo Ciarlante <jjo@irrigacion.gov.ar>
 9 # Lightly reformatted by ABS Guide author.
10 # License: GPLv2
11 # Used in ABS Guide with author's permission (thanks!).
13 # Test with: ./insertion-sort.bash -t
14 # Or: bash insertion-sort.bash -t
15 # The following *doesn't* work:
                sh insertion-sort.bash -t
16 #
17 # Why not? Hint: which Bash-specific features are disabled
18 #+ when running a script by 'sh script.sh'?
```

```
19 #
20 : ${DEBUG:=0} # Debug, override with: DEBUG=1 ./scriptname . . .

10 #
                Edited for layout by M.C.
11 # (author of the "Advanced Bash Scripting Guide")
12
13
14 # This script tested under Bash versions 2.04, 2.05a and 2.05b.
15 # It may not work with earlier versions.
16 # This demonstration script generates one --intentional--
17 #+ "command not found" error message. See line 394.
19 # The current Bash maintainer, Chet Ramey, has fixed the items noted
20 #+ for an upcoming version of Bash.
21

30
         ###-----###
31
32
33
34 # Most of the following points are described at length in
35 #+ the text of the foregoing "Advanced Bash Scripting Guide."
36 \ \# This demonstration script is mostly just a reorganized presentation.
        -- msz
37 #
38
39 # Variables are not typed unless otherwise specified.
40
41 # Variables are named. Names must contain a non-digit.
42 # File descriptor names (as in, for example: 2>&1)
43 #+ contain ONLY digits.
45 # Parameters and Bash array elements are numbered.
46 # (Parameters are very similar to Bash arrays.)
48 # A variable name may be undefined (null reference).
49 unset VarNull
50
51 # A variable name may be defined but empty (null contents).
52 VarEmpty=''
                                    # Two, adjacent, single quotes.
54 # A variable name my be defined and non-empty
55 VarSomething='Literal'
56
57 # A variable may contain:
58 \# * A whole number as a signed 32-bit (or larger) integer
```

```
59 # * A string
 60 # A variable may also be an array.
 62 # A string may contain embedded blanks and may be treated
 63 #+ as if it where a function name with optional arguments.
 65 # The names of variables and the names of functions
 66 #+ are in different namespaces.
 67
 68
 69 # A variable may be defined as a Bash array either explicitly or
 70 #+ implicitly by the syntax of the assignment statement.
 71 # Explicit:
 72 declare -a ArrayVar
 73
 74
 76 # The echo command is a built-in.
 77 echo $VarSomething
79 # The printf command is a built-in.
80 # Translate %s as: String-Format
81 printf %s $VarSomething # No linebreak specified, none output.
                                    # Default, only linebreak output.
82 echo
8.3
84
85
86
87 # The Bash parser word breaks on whitespace.
88 # Whitespace, or the lack of it is significant.
89 # (This holds true in general; there are, of course, exceptions.)
90
91
92
93
94 # Translate the DOLLAR_SIGN character as: Content-Of.
 96 # Extended-Syntax way of writing Content-Of:
 97 echo ${VarSomething}
98
99 \# The \{ \dots \} Extended-Syntax allows more than just the variable
100 #+ name to be specified.
101 # In general, $VarSomething can always be written as: ${VarSomething}.
103 # Call this script with arguments to see the following in action.
104
105
106
107 \# Outside of double-quotes, the special characters @ and *
108 #+ specify identical behavior.
109 # May be pronounced as: All-Elements-Of.
110
111 # Without specification of a name, they refer to the
112 #+ pre-defined parameter Bash-Array.
113
114
115
116 # Glob-Pattern references
117 echo $*
                                    # All parameters to script or function
118 echo ${*}
                                    # Same
119
120 # Bash disables filename expansion for Glob-Patterns.
121 # Only character matching is active.
122
123
124 # All-Elements-Of references
```

```
125 echo $@
                                    # Same as above
126 echo ${@}
                                    # Same as above
127
128
129
130
131 # Within double-quotes, the behavior of Glob-Pattern references
132 #+ depends on the setting of IFS (Input Field Separator).
133 # Within double-quotes, All-Elements-Of references behave the same.
134
135
136 # Specifying only the name of a variable holding a string refers
137 #+ to all elements (characters) of a string.
138
139
140 # To specify an element (character) of a string,
141 #+ the Extended-Syntax reference notation (see below) MAY be used.
142
143
144
145
146 # Specifying only the name of a Bash array references
147 #+ the subscript zero element,
148 #+ NOT the FIRST DEFINED nor the FIRST WITH CONTENTS element.
149
150 # Additional qualification is needed to reference other elements,
151 #+ which means that the reference MUST be written in Extended-Syntax.
152 # The general form is: ${name[subscript]}.
153
154 # The string forms may also be used: ${name:subscript}
155 #+ for Bash-Arrays when referencing the subscript zero element.
156
157
158 # Bash-Arrays are implemented internally as linked lists,
159 #+ not as a fixed area of storage as in some programming languages.
160
161
162 # Characteristics of Bash arrays (Bash-Arrays):
163 #
164
165 #
      If not otherwise specified, Bash-Array subscripts begin with
166 #+ subscript number zero. Literally: [0]
167 #
      This is called zero-based indexing.
168 ###
169 # If not otherwise specified, Bash-Arrays are subscript packed
170 #+ (sequential subscripts without subscript gaps).
171 ###
172 # Negative subscripts are not allowed.
173 ###
174 # Elements of a Bash-Array need not all be of the same type.
175 ###
176 # Elements of a Bash-Array may be undefined (null reference).
177 #
           That is, a Bash-Array my be "subscript sparse."
178 ###
179 \# Elements of a Bash-Array may be defined and empty (null contents).
180 ###
181 #
       Elements of a Bash-Array may contain:
182 #
        * A whole number as a signed 32-bit (or larger) integer
183 #
         * A string
184 #
         * A string formated so that it appears to be a function name
185 #
         + with optional arguments
186 ###
187 # Defined elements of a Bash-Array may be undefined (unset).
188 #
        That is, a subscript packed Bash-Array may be changed
189 # + into a subscript sparse Bash-Array.
190 ###
```

```
Elements may be added to a Bash-Array by defining an element
192 #+ not previously defined.
193 ###
194 # For these reasons, I have been calling them "Bash-Arrays".
195 # I'll return to the generic term "array" from now on.
        -- msz
197
198
199
200
201 # Demo time -- initialize the previously declared ArrayVar as a
202 #+ sparse array.
203 # (The 'unset ... ' is just documentation here.)
204
205 unset ArrayVar[0]
                                       # Just for the record
206 ArrayVar[1]=one
                                       # Unquoted literal
207 ArrayVar[2]=''
                                       # Defined, and empty

236 echo
237 echo 'echo command: '"${ArrayVar[*]}"
238 ###
239 printf %q "${ArrayVar[@]}"
                                     # All-Elements-Of
240 echo
241 echo 'echo command: '"${ArrayVar[@]}"
242
243
244 echo
245 echo '- - Within double-quotes - First character of IFS is ^ - -'
246 # Any printing, non-whitespace character should do the same.
247 IFS='^'$IFS
                                      # ^ + space tab newline
248 ###
249 printf %q "${ArrayVar[*]}" # Glob-Pattern All-Elements-Of
250 echo
251 echo 'echo command:'"${ArrayVar[*]}"
252 ###
253 printf %q "${ArrayVar[@]}" # All-Elements-Of
254 echo
255 echo 'echo command:'"${ArrayVar[@]}"
256
```

```
257
258 echo
259 echo '- - Within double-quotes - Without whitespace in IFS - -'
260 IFS='^:%!'
261 ###
262 printf %q "${ArrayVar[*]}"
                                      # Glob-Pattern All-Elements-Of
263 echo
264 echo 'echo command: '"${ArrayVar[*]}"
265 ###
266 printf %q "${ArrayVar[@]}"
                                      # All-Elements-Of
267 echo
268 echo 'echo command: '"${ArrayVar[@]}"
269
270
271 echo
272 echo '- - Within double-quotes - IFS set and empty - -'
273 IFS=''
274 ###
275 printf %q "${ArrayVar[*]}" # Glob-Pattern All-Elements-Of
276 echo
277 echo 'echo command: '"${ArrayVar[*]}"
278 ###
279 printf %q "${ArrayVar[@]}" # All-Elements-Of
280 echo
281 echo 'echo command:'"${ArrayVar[@]}"
282
283
284 echo
285 echo '- - Within double-quotes - IFS undefined - -'
286 unset IFS
287 ###
288 printf %q "${ArrayVar[*]}"
                                      # Glob-Pattern All-Elements-Of
289 echo
290 echo 'echo command: '"${ArrayVar[*]}"
291 ###
292 printf %q "${ArrayVar[@]}"
                                      # All-Elements-Of
293 echo
294 echo 'echo command: '"${ArrayVar[@]}"
295
296
297 # Put IFS back to the default.
298 # Default is exactly these three bytes.
299 IFS=$'\x20'$'\x09'$'\x0A'
                                      # In exactly this order.
300
301 # Interpretation of the above outputs:
302 \# A Glob-Pattern is I/O; the setting of IFS matters.
303 ###
304 # An All-Elements-Of does not consider IFS settings.
305 ###
306 # Note the different output using the echo command and the
307 #+ quoted format operator of the printf command.
308
309
310 # Recall:
311 # Parameters are similar to arrays and have the similar behaviors.
312 ###
313 # The above examples demonstrate the possible variations.
314 # To retain the shape of a sparse array, additional script
315 #+ programming is required.
316 ###
317 # The source code of Bash has a routine to output the
318 #+ [subscript]=value array assignment format.
319 # As of version 2.05b, that routine is not used,
320 #+ but that might change in future releases.
321
322
```

```
323
324 # The length of a string, measured in non-null elements (characters):
326 echo '- - Non-quoted references - -'
327 echo 'Non-Null character count: '${#VarSomething}' characters.'
329 # test='Lit'$'\x00''eral'
                                       # $'\x00' is a null character.
330 # echo ${#test}
                                        # See that?
331
332
333
334 # The length of an array, measured in defined elements,
335 #+ including null content elements.
337 echo 'Defined content count: '${#ArrayVar[@]}' elements.'
338 # That is NOT the maximum subscript (4).
339 # That is NOT the range of the subscripts (1 . . 4 inclusive).
340 # It IS the length of the linked list.
341 ###
342 # Both the maximum subscript and the range of the subscripts may
343 #+ be found with additional script programming.
344
345 # The length of a string, measured in non-null elements (characters):
346 echo
347 echo '- - Quoted, Glob-Pattern references - -'
348 echo 'Non-Null character count: '"${#VarSomething}"' characters.'
350 # The length of an array, measured in defined elements,
351 #+ including null-content elements.
352 echo
353 echo 'Defined element count: '"${#ArrayVar[*]}"' elements.'
354
355 # Interpretation: Substitution does not effect the \{# ... } operation.
356 # Suggestion:
357 # Always use the All-Elements-Of character
358 #+ if that is what is intended (independence from IFS).
359
360
361
362 # Define a simple function.
363 # I include an underscore in the name
364 \#+ to make it distinctive in the examples below.
365 ###
366 # Bash separates variable names and function names
367 #+ in different namespaces.
368 # The Mark-One eyeball isn't that advanced.
369 ###
370 _simple() {
371 echo -n 'SimpleFunc'$@
                                       # Newlines are swallowed in
372 }
                                        #+ result returned in any case.
373
374
375 \ \# \ \text{The} \ ( \ \dots \ ) \ \text{notation invokes a command or function.}
376 \# The \$( ... ) notation is pronounced: Result-Of.
377
378
379 # Invoke the function _simple
380 echo
381 echo '- - Output of function _simple - -'
382 _simple
                                        # Try passing arguments.
383 echo
384 # or
385 (_simple)
                                         # Try passing arguments.
386 echo
387
388 echo '- Is there a variable of that name? -'
```

```
389 echo $_simple not defined # No variable by that name.

483 #+ "protect_literal.sh" and "unprotect_literal.sh" examples.
484 # These are general purpose functions for delayed replacement literals
485 #+ containing variables.
486
487
488
489
490
491 # REVIEW:
492 # -----
494 # A string can be considered a Classic-Array of elements (characters).
495 # A string operation applies to all elements (characters) of the string
496 #+ (in concept, anyway).
497 ###
498 # The notation: ${array_name[@]} represents all elements of the
499 #+ Bash-Array: array_name.
500 ###
501 # The Extended-Syntax string operations can be applied to all
502 #+ elements of an array.
504 # This may be thought of as a For-Each operation on a vector of strings.
505 ###
506 # Parameters are similar to an array.
507 # The initialization of a parameter array for a script
508 #+ and a parameter array for a function only differ
509 \#+ in the initialization of \{0\}, which never changes its setting.
510 ###
511 # Subscript zero of the script's parameter array contains
512 #+ the name of the script.
513 ###
514 # Subscript zero of a function's parameter array DOES NOT contain
515 #+ the name of the function.
516 # The name of the current function is accessed by the $FUNCNAME variable.
517 ###

Advanced Bash-Scripting Guide: An in-depth exploration of the art of shell scripting
Prev Next

Appendix B. Reference Cards

The following reference cards provide a useful *summary* of certain scripting concepts. The foregoing text treats these matters in more depth, as well as giving usage examples.

Table B-1. Special Shell Variables

Variable	Meaning
\$0	Filename of script
\$1	Positional parameter #1
\$2 - \$9	Positional parameters #2 - #9
\${10}	Positional parameter #10
\$#	Number of positional parameters
"\$*"	All the positional parameters (as a single word) *
"\$@"	All the positional parameters (as separate strings)
\${#*}	Number of command line parameters passed to script
\${#@}	Number of command line parameters passed to script
\$?	Return value
\$\$	Process ID (PID) of script
\$-	Flags passed to script (using set)
\$_	Last argument of previous command
\$!	Process ID (PID) of last job run in background

^{*} Must be quoted, otherwise it defaults to "\$@".

Table B-2. TEST Operators: Binary Comparison

Operator	Meaning	 Operator	Meaning
Arithmetic Comparison		String Comparison	
-eq	Equal to	=	Equal to
		==	Equal to
-ne	Not equal to	!=	Not equal to
-lt	Less than	\<	Less than (ASCII) *
-le	Less than or equal to		
-gt	Greater than	\>	Greater than (ASCII) *
-ge	Greater than or equal to		
		-z	String is empty
		-n	String is not empty
Arithmetic Comparison	within double parentheses (())		
>	Greater than		

>=	Greater than or equal to		
<	Less than		
<=	Less than or equal to		

^{*} If within a double-bracket [[...]] test construct, then no escape $\$ is needed.

Table B-3. TEST Operators: Files

Operator	Tests Whether	 Operator	Tests Whether
-е	File exists	-s	File is not zero size
-f	File is a regular file		
-d	File is a <i>directory</i>	-r	File has read permission
-h	File is a symbolic link	-M	File has write permission
-L	File is a symbolic link	-x	File has execute permission
-b	File is a <i>block device</i>		
-c	File is a character device	-g	sgid flag set
-p	File is a pipe	-u	suid flag set
-S	File is a socket	-k	"sticky bit" set
-t	File is associated with a terminal		
-N	File modified since it was last read	F1 -nt F2	File F1 is <i>newer</i> than F2 *
-0	You own the file	F1 -ot F2	File F1 is <i>older</i> than F2 *
-G	Group id of file same as yours	F1 -ef F2	Files F1 and F2 are <i>hard links</i> to the same file *
!	"NOT" (reverses sense of above tests)		

^{*} Binary operator (requires two operands).

Table B-4. Parameter Substitution and Expansion

Expression	Meaning
\${var}	Value of var, same as \$var
<pre>\${var-DEFAULT}</pre>	If var not set, evaluate expression as \$DEFAULT*
<pre>\${var:-DEFAULT}</pre>	If var not set or is empty, evaluate expression as \$DEFAULT*
<pre>\${var=DEFAULT}</pre>	If var not set, evaluate expression as \$DEFAULT*
<pre>\${var:=DEFAULT}</pre>	If var not set, evaluate expression as \$DEFAULT*
\${var+OTHER}	If var set, evaluate expression as \$OTHER, otherwise as null string
<pre>\${var:+OTHER}</pre>	If var set, evaluate expression as \$OTHER, otherwise as null string

\${var?ERR_MSG}	If var not set, print \$ERR_MSG*
<pre>\${var:?ERR_MSG}</pre>	If var not set, print \$ERR_MSG*
<pre>\${!varprefix*}</pre>	Matches all previously declared variables beginning with varprefix
<pre>\${!varprefix@}</pre>	Matches all previously declared variables beginning with varprefix

^{*} Of course if var is set, evaluate the expression as \$var.

Table B-5. String Operations

Expression	Meaning
\${#string}	Length of \$string
\${string:position}	Extract substring from \$string at \$position
<pre>\${string:position:length}</pre>	Extract \$length characters substring from \$string at \$position
\${string#substring}	Strip shortest match of \$substring from front of \$string
\${string##substring}	Strip longest match of \$substring from front of \$string
\${string%substring}	Strip shortest match of \$substring from back of \$string
\${string%%substring}	Strip longest match of \$substring from back of \$string
\${string/substring/replacement}	Replace first match of \$substring with \$replacement
\${string//substring/replacement}	Replace all matches of \$substring with \$replacement
\${string/#substring/replacement}	If \$substring matches front end of \$string, substitute \$replacement for \$substring
\${string/%substring/replacement}	If \$substring matches back end of \$string, substitute \$replacement for \$substring
expr match "\$string" '\$substring'	Length of matching \$substring* at beginning of
	\$string
expr "\$string" : '\$substring'	Length of matching \$substring* at beginning of \$string
expr index "\$string" \$substring	Numerical position in \$string of first character in \$substring that matches
expr substr \$string \$position \$length	Extract \$length characters from \$string starting at \$position
	Extract \$substring* at beginning of \$string

<pre>expr match "\$string" '\(\$substring\)'</pre>	
<pre>expr "\$string" : '\(\$substring\)'</pre>	Extract \$substring* at beginning of \$string
<pre>expr match "\$string" '.*\(\$substring\)'</pre>	Extract \$substring* at end of \$string
<pre>expr "\$string" : '.*\(\$substring\)'</pre>	Extract \$substring* at end of \$string

^{*} Where \$substring is a regular expression.

Table B-6. Miscellaneous Constructs

Expression	Interpretation
<u>Brackets</u>	
if [CONDITION]	Test construct
if [[CONDITION]]	Extended test construct
Array[1]=element1	Array initialization
[a-z]	Range of characters within a Regular Expression
Curly Brackets	
\${variable}	Parameter substitution
<pre>\${!variable}</pre>	Indirect variable reference
<pre>{ command1; command2; commandN; }</pre>	Block of code
{string1,string2,string3,}	Brace expansion
{az}	Extended brace expansion
{}	Text replacement, after <u>find</u> and <u>xargs</u>
<u>Parentheses</u>	
(command1; command2)	Command group executed within a <u>subshell</u>
Array=(element1 element2 element3)	Array initialization
result=\$(COMMAND)	Execute command in subshell and assign result to variable
> (COMMAND)	Process substitution
<(COMMAND)	Process substitution
Double Parentheses	
((var = 78))	Integer arithmetic
var=\$((20 + 5))	Integer arithmetic, with variable assignment
((var++))	C-style variable increment
((var))	C-style variable decrement
((var0 = var1<98?9:21))	C-style trinary operation

Quoting	
"\$variable"	"Weak" quoting
'string'	"Strong" quoting
Back Quotes	
result=`COMMAND`	Execute command in subshell and assign result to
	variable

Contributed Scripts A Sed and Awk Micro-Primer
Advanced Bash-Scripting Guide: An in-depth exploration of the art of shell scripting
Prev Next

Appendix C. A Sed and Awk Micro-Primer

This is a very brief introduction to the **sed** and **awk** text processing utilities. We will deal with only a few basic commands here, but that will suffice for understanding simple sed and awk constructs within shell scripts.

sed: a non-interactive text file editor

awk: a field-oriented pattern processing language with a C-style syntax

For all their differences, the two utilities share a similar invocation syntax, both use regular expressions, both read input by default from stdin, and both output to stdout. These are well-behaved UNIX tools, and they work together well. The output from one can be piped into the other, and their combined capabilities give shell scripts some of the power of Perl.

One important difference between the utilities is that while shell scripts can easily pass arguments to sed, it is more complicated for awk (see Example 33-5 and Example 9-25).

C.1. Sed

Sed is a non-interactive line editor. It receives text input, whether from stdin or from a file, performs certain operations on specified lines of the input, one line at a time, then outputs the result to stdout or to a file. Within a shell script, sed is usually one of several tool components in a pipe.

Sed determines which lines of its input that it will operate on from the *address range* passed to it. [1] Specify this address range either by line number or by a pattern to match. For example, 3d signals sed to delete line 3 of the input, and /windows/d tells sed that you want every line of the input containing a match to "windows" deleted.

Of all the operations in the sed toolkit, we will focus primarily on the three most commonly used ones. These are **p**rinting (to stdout), **d**eletion, and **s**ubstitution.

Table C-1. Basic sed operators

Operator	Name	Effect
[address-range]/p	print	Print [specified address range]
[address-range]/d	delete	Delete [specified address range]
s/pattern1/pattern2/	substitute	Substitute pattern2 for first instance of pattern1 in a line
[address-range]/s/pattern1/pattern2/	substitute	Substitute pattern2 for first instance of pattern1 in a line, over address-range
[address-range]/y/pattern1/pattern2/	transform	replace any character in pattern1 with the corresponding character in pattern2, over address-range (equivalent of tr)
g	global	Operate on <i>every</i> pattern match within each matched line of input

Unless the g (*global*) operator is appended to a *substitute* command, the substitution operates only on the first instance of a pattern match within each line.

From the command line and in a shell script, a sed operation may require quoting and certain options.

```
1 sed -e '/^$/d' $filename
2 # The -e option causes the next string to be interpreted as an editing instruction.
3 # (If passing only a single instruction to sed, the "-e" is optional.)
4 # The "strong" quotes ('') protect the RE characters in the instruction
5 #+ from reinterpretation as special characters by the body of the script.
6 # (This reserves RE expansion of the instruction for sed.)
7 #
8 # Operates on the text contained in file $filename.
```

In certain cases, a *sed* editing command will not work with single quotes.

Sed uses the -e option to specify that the following string is an instruction or set of instructions. If there is only a single instruction contained in the string, then this may be omitted.

```
1 sed -n '/xzy/p' $filename
2 # The -n option tells sed to print only those lines matching the pattern.
3 # Otherwise all input lines would print.
4 # The -e option not necessary here since there is only a single editing instruction.
```

Table C-2. Examples of sed operators

Notation	Effect	
8d	Delete 8th line of input.	
/^\$/d	Delete all blank lines.	
1,/^\$/d	Delete from beginning of input up to, and including first blank line.	
/Jones/p	Print only lines containing "Jones" (with -n option).	
s/Windows/Linux/	Substitute "Linux" for first instance of "Windows" found in each input line.	
s/BSOD/stability/g	Substitute "stability" for every instance of "BSOD" found in each input line.	
s/ *\$//	Delete all spaces at the end of every line.	
s/00*/0/g	Compress all consecutive sequences of zeroes into a single zero.	
/GUI/d	Delete all lines containing "GUI".	
s/GUI//g	Delete all instances of "GUI", leaving the remainder of each line intact.	

Substituting a zero-length string for another is equivalent to deleting that string within a line of input. This leaves the remainder of the line intact. Applying **s/GUI//** to the line

The most important parts of any application are its GUI and sound effects results in

```
The most important parts of any application are its and sound effects
```

A backslash forces the **sed** replacement command to continue on to the next line. This has the effect of using the *newline* at the end of the first line as the *replacement string*.

```
1 s/^ */\
2 /g
```

This substitution replaces line-beginning spaces with a newline. The net result is to replace paragraph indents with a blank line between paragraphs.

An address range followed by one or more operations may require open and closed curly brackets, with appropriate newlines.

```
1 /[0-9A-Za-z]/,/^$/{
2 /^$/d
3 }
```

This deletes only the first of each set of consecutive blank lines. That might be useful for single-spacing a text file, but retaining the blank line(s) between paragraphs.

The usual delimiter that *sed* uses is /. However, *sed* allows other delimiters, such as %. This is useful when / is part of a replacement string, as in a file pathname. See Example 10-9 and Example 15-31.

(i) A quick way to double-space a text file is sed G filename.

For illustrative examples of sed within shell scripts, see:

- 1. Example 33-1

- 18. Example 15-18
- 19. Example A-31
- 20. Example A-26

For a more extensive treatment of sed, check the appropriate references in the <u>Bibliography</u>.

Notes

[1] If no address range is specified, the default is *all* lines.

<u>Prev</u>	<u>Home</u> Ne	ext		
Reference Cards	A	wk		
Advanced Bash-Scripting Guide: An in-depth exploration of the art of shell scripting				
Prev Appendix C. A S	sed and Awk Micro-Primer Ne	<u>ext</u>		

C.2. Awk

Awk is a full-featured text processing language with a syntax reminiscent of **C**. While it possesses an extensive set of operators and capabilities, we will cover only a couple of these here - the ones most useful for shell scripting.

Awk breaks each line of input passed to it into *fields*. By default, a field is a string of consecutive characters delimited by <u>whitespace</u>, though there are options for changing this. Awk parses and operates on each separate field. This makes it ideal for handling structured text files -- especially tables -- data organized into consistent chunks, such as rows and columns.

Strong quoting and curly brackets enclose blocks of awk code within a shell script.

```
1 # $1 is field #1, $2 is field #2, etc.
 3 echo one two | awk '{print $1}'
 6 echo one two | awk '{print $2}'
7 # two
 8
 9 # But what is field #0 ($0)?
10 echo one two | awk '{print $0}'
11 # one two
12 # All the fields!
13
15 awk '{print $3}' $filename
16 # Prints field #3 of file $filename to stdout.
18 awk '{print $1 $5 $6}' $filename
19 # Prints fields #1, #5, and #6 of file $filename.
21 awk '{print $0}' $filename
22 # Prints the entire file!
23 \# Same effect as: cat $filename . . . or . . . sed '' $filename
```

We have just seen the awk **print** command in action. The only other feature of awk we need to deal with here is variables. Awk handles variables similarly to shell scripts, though a bit more flexibly.

```
1 { total += ${column_number} }
```

This adds the value of column_number to the running total of total>. Finally, to print "total", there is an **END** command block, executed after the script has processed all its input.

```
1 END { print total }
```

Corresponding to the **END**, there is a **BEGIN**, for a code block to be performed before awk starts processing its input.

The following example illustrates how **awk** can add text-parsing tools to a shell script.

Example C-1. Counting Letter Occurrences

```
1 #! /bin/sh
2 # letter-count2.sh: Counting letter occurrences in a text file.
3 #
4 # Script by nyal [nyal@voila.fr].
5 # Used in ABS Guide with permission.
6 # Recommented and reformatted by ABS Guide author.
```

```
7 # Version 1.1: Modified to work with gawk 3.1.3.
                 (Will still work with earlier versions.)
9
10
11 INIT_TAB_AWK=""
12 # Parameter to initialize awk script.
13 count case=0
14 FILE_PARSE=$1
15
16 E_PARAMERR=65
17

A Sed and Awk Micro-Primer Up Exit Codes With Special Meanings
Advanced Bash-Scripting Guide: An in-depth exploration of the art of shell scripting

Prev Next

Appendix D. Exit Codes With Special Meanings

Table D-1. Reserved Exit Codes

Exit Code Number	Meaning	Example	Comments
1	Catchall for general errors	let "var1 = 1/0"	Miscellaneous errors, such as "divide by zero"
2	Misuse of shell builtins (according to Bash documentation)		Seldom seen, usually defaults to exit code 1
126	Command invoked cannot execute		Permission problem or command is not an executable
127	"command not found"		Possible problem with \$PATH or a typo
128	Invalid argument to exit	exit 3.14159	exit takes only integer args in the range 0 - 255 (see footnote)
128+n	Fatal error signal "n"	kill -9 \$PPID of script	\$? returns 137 (128 + 9)
130	Script terminated by Control-C		Control-C is fatal error signal 2, (130 = 128 + 2, see above)
255*	Exit status out of range	exit -1	exit takes only integer args in the range 0 - 255

According to the above table, exit codes 1 - 2, 126 - 165, and 255 [1] have special meanings, and should therefore be avoided for user-specified exit parameters. Ending a script with **exit 127** would certainly cause confusion when troubleshooting (is the error code a "command not found" or a user-defined one?). However, many scripts use an **exit 1** as a general bailout upon error. Since exit code 1 signifies so many possible errors, this probably would not be helpful in debugging.

There has been an attempt to systematize exit status numbers (see /usr/include/sysexits.h), but this is intended for C and C++ programmers. A similar standard for scripting might be appropriate. The author of this document proposes restricting user-defined exit codes to the range 64 - 113 (in addition to 0, for success), to conform with the C/C++ standard. This would allot 50 valid codes, and make troubleshooting scripts more straightforward.

All user-defined exit codes in the accompanying examples to this document now conform to this standard, except where overriding circumstances exist, as in <u>Example 9-2</u>.

Issuing a <u>\$?</u> from the command line after a shell script exits gives results consistent with the table above only from the Bash or *sh* prompt. Running the *C-shell* or *tcsh* may give different values in some cases.

Notes

Out of range exit values can result in unexpected exit codes. An exit value greater than 255 returns an exit code modulo 256. For example, exit 3809 gives an exit code of 225 (3809 % 256 = 225).

		I/O Redirection
	Advanced Bash-Scripting Guide: An in-depth exploration of	f the art of shell scripting
<u>Prev</u>		<u>Next</u>

Appendix E. A Detailed Introduction to I/O and I/O Redirection

written by Stéphane Chazelas, and revised by the document author

A command expects the first three <u>file descriptors</u> to be available. The first, $fd\ 0$ (standard input, stdin), is for reading. The other two ($fd\ 1$, stdout and $fd\ 2$, stderr) are for writing.

There is a stdin, stdout, and a stderr associated with each command. **1s 2>&1** means temporarily connecting the stderr of the **ls** command to the same "resource" as the shell's stdout.

By convention, a command reads its input from fd 0 (stdin), prints normal output to fd 1 (stdout), and error output to fd 2 (stderr). If one of those three fd's is not open, you may encounter problems:

```
bash$ cat /etc/passwd >&-
cat: standard output: Bad file descriptor
```

For example, when **xterm** runs, it first initializes itself. Before running the user's shell, **xterm** opens the terminal device (/dev/pts/<n> or something similar) three times.

At this point, Bash inherits these three file descriptors, and each command (child process) run by Bash inherits them in turn, except when you redirect the command. Redirection means reassigning one of the file descriptors to another file (or a pipe, or anything permissible). File descriptors may be reassigned locally (for a command, a command group, a subshell, a while or if or case or for loop...), or globally, for the remainder of the shell (using exec).

ls > /dev/null means running ls with its fd 1 connected to /dev/null.

```
bash$ lsof -a -p $$ -d0,1,2

COMMAND PID USER FD TYPE DEVICE SIZE NODE NAME

bash 363 bozo 0u CHR 136,1 3 /dev/pts/1

bash 363 bozo 1u CHR 136,1 3 /dev/pts/1

bash 363 bozo 2u CHR 136,1 3 /dev/pts/1

bash 363 bozo 2u CHR 136,1 3 /dev/pts/1

bash$ lsof -a -p $$ -d0,1,2

COMMAND PID USER FD TYPE DEVICE SIZE NODE NAME

bash 371 bozo 0u CHR 136,1 3 /dev/pts/1

bash 371 bozo 1u CHR 136,1 3 /dev/pts/1

bash 371 bozo 2w CHR 1,3 120 /dev/null

bash$ bash -c 'lsof -a -p $$ -d0,1,2' | cat

COMMAND PID USER FD TYPE DEVICE SIZE NODE NAME

lsof 379 root 0u CHR 136,1 3 /dev/pts/1

lsof 379 root 1w FIFO 0,0 7118 pipe

lsof 379 root 2u CHR 136,1 3 /dev/pts/1

bash$ echo "$(bash -c 'lsof -a -p $$ -d0,1,2' 2>&1)"

COMMAND PID USER FD TYPE DEVICE SIZE NODE NAME

lsof 379 root 0u CHR 136,1 3 /dev/pts/1

bash$ echo "$(bash -c 'lsof -a -p $$ -d0,1,2' 2>&1)"

COMMAND PID USER FD TYPE DEVICE SIZE NODE NAME

lsof 426 root 0u CHR 136,1 3 /dev/pts/1

lsof 426 root 1w FIFO 0,0 7520 pipe

lsof 426 root 2w FIFO 0,0 7520 pipe
```

This works for different types of redirection.

```
1 #! /usr/bin/env bash
3 mkfifo /tmp/fifo1 /tmp/fifo2
 4 while read a; do echo "FIFO1: $a"; done < /tmp/fifo1 & exec 7> /tmp/fifo1
 5 exec 8> >(while read a; do echo "FD8: $a, to fd7"; done >&7)
7 exec 3>&1

Prev Next

Appendix F. Command-Line Options

Many executables, whether binaries or script files, accept options to modify their run-time behavior. For example: from the command line, typing **command -o** would invoke *command*, with option \circ .

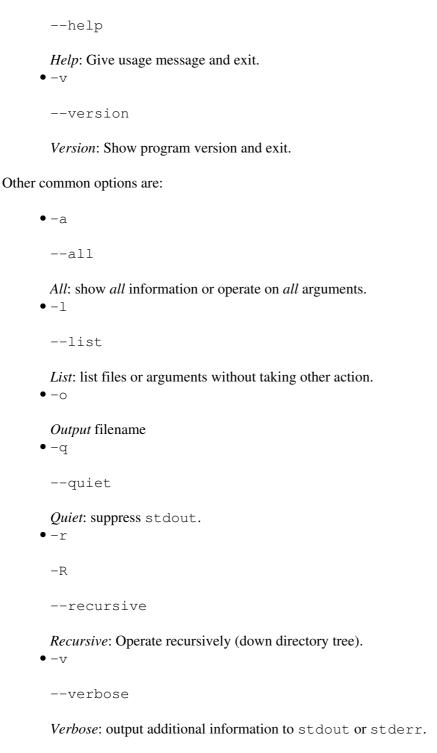

F.1. Standard Command-Line Options

Over time, there has evolved a loose standard for the meanings of command line option flags. The GNU utilities conform more closely to this "standard" than older UNIX utilities.

Traditionally, UNIX command-line options consist of a dash, followed by one or more lowercase letters. The GNU utilities added a double-dash, followed by a complete word or compound word.

● -h

However:

- In tar and gawk:
 - -f
 - --file

File: filename follows.

- In cp, mv, rm:
 - -f
 - --force

Force: force overwrite of target file(s).

Many UNIX and Linux utilities deviate from this "standard," so it is dangerous to *assume* that a given option will behave in a standard way. Always check the man page for the command in question when in doubt.

A complete table of recommended options for the GNU utilities is available at the GNU standards page.

A Detailed Introduction to I/O and Bash Command-Line Options
I/O Redirection

Advanced Bash-Scripting Guide: An in-depth exploration of the art of shell scripting

<u>Prev</u> Appendix F. Command-Line Options <u>Next</u>

F.2. Bash Command-Line Options

Bash itself has a number of command-line options. Here are some of the more useful ones.

• -c

Read commands from the following string and assign any arguments to the <u>positional parameters</u>.

```
bash$ bash -c 'set a b c d; IFS="+-;"; echo "$*"' a+b+c+d
```

• -r

--restricted

Runs the shell, or a script, in <u>restricted mode</u>.

• --posix

Forces Bash to conform to <u>POSIX</u> mode.

• --version

Display Bash version information and exit.

• --

End of options. Anything further on the command line is an argument, not an option.

Command-Line Options Up Important Files
Advanced Bash-Scripting Guide: An in-depth exploration of the art of shell scripting
Prev Next

Appendix G. Important Files

startup files

These files contain the aliases and <u>environmental variables</u> made available to Bash running as a user shell and to all Bash scripts invoked after system initialization.

/etc/profile

Systemwide defaults, mostly setting the environment (all Bourne-type shells, not just Bash [1]) /etc/bashrc

systemwide functions and aliases for Bash

\$HOME/.bash_profile

user-specific Bash environmental default settings, found in each user's home directory (the local counterpart to /etc/profile)

\$HOME/.bashrc

user-specific Bash init file, found in each user's home directory (the local counterpart to /etc/bashrc). Only interactive shells and user scripts read this file. See <u>Appendix K</u> for a sample .bashrc file.

logout file

\$HOME/.bash_logout

user-specific instruction file, found in each user's home directory. Upon exit from a login (Bash) shell, the commands in this file execute.

system configuration files

/etc/sysconfig/hwconf

Bash Command-Line Options

Listing and description of attached hardware devices. This information is in text form and can be extracted and parsed.

```
bash$ grep -A 5 AUDIO /etc/sysconfig/hwconf
class: AUDIO
bus: PCI
detached: 0
driver: snd-intel8x0
desc: "Intel Corporation 82801CA/CAM AC'97 Audio Controller"
vendorId: 8086
```

This file is present on Red Hat and Fedora Core installations, but may be missing from other distros.

Notes

[1] This does not apply to **csh**, **tcsh**, and other shells not related to or descended from the classic Bourne shell (**sh**).

Important System Directories

Advanced Bash-Scripting Guide: An in-depth exploration of the art of shell scripting

<u>Prev</u> Next

Appendix H. Important System Directories

Sysadmins and anyone else writing administrative scripts should be intimately familiar with the following system directories.

•/bin

Binaries (executables). Basic system programs and utilities (such as bash).

• /usr/bin [1]

More system binaries.

• /usr/local/bin

Miscellaneous binaries local to the particular machine.

•/sbin

System binaries. Basic system administrative programs and utilities (such as **fsck**).

• /usr/sbin

More system administrative programs and utilities.

• /etc

Et cetera. Systemwide configuration scripts.

Of particular interest are the /etc/fstab (filesystem table), /etc/mtab (mounted filesystem table), and the /etc/inittab files.

• /etc/rc.d

Boot scripts, on Red Hat and derivative distributions of Linux.

• /usr/share/doc

Documentation for installed packages.

• /usr/man

The systemwide manpages.

• /dev

Device directory. Entries (but not mount points) for physical and virtual devices. See Chapter 27.

• /proc

Process directory. Contains information and statistics about running processes and kernel parameters. See <u>Chapter 27</u>.

•/sys

Systemwide device directory. Contains information and statistics about device and device names. This is newly added to Linux with the 2.6.X kernels.

• /mnt

Mount. Directory for mounting hard drive partitions, such as /mnt/dos, and physical devices. In newer Linux distros, the /media directory has taken over as the preferred mount point for I/O devices.

• /media

In newer Linux distros, the preferred mount point for I/O devices, such as CD ROMs or USB flash drives.

• /var

Variable (changeable) system files. This is a catchall "scratchpad" directory for data generated while a Linux/UNIX machine is running.

•/var/log

Systemwide log files.

• /var/spool/mail

User mail spool.

•/lib

Systemwide library files.

• /usr/lib

More systemwide library files.

• /tmp

System temporary files.

• /boot

System boot directory. The kernel, module links, system map, and boot manager reside here.

Altering files in this directory may result in an unbootable system.

Notes

[1] Some early UNIX systems had a fast, small-capacity fixed disk (containing /, the root partition), and a second drive which was larger, but slower (containing /usr and other partitions). The most frequently used programs and utilities therefore resided on the small-but-fast drive, in /bin, and the others on the slower drive, in /usr/bin.

This likewise accounts for the split between /sbin and /usr/sbin, /lib and /usr/lib, etc.

Important Files Localization
Advanced Bash-Scripting Guide: An in-depth exploration of the art of shell scripting
Prev Next

Appendix I. Localization

Localization is an undocumented Bash feature.

A localized shell script echoes its text output in the language defined as the system's locale. A Linux user in Berlin, Germany, would get script output in German, whereas his cousin in Berlin, Maryland, would get output from the same script in English.

To create a localized script, use the following template to write all messages to the user (error messages, prompts, etc.).

```
1 #!/bin/bash
 2 # localized.sh
 3 # Script by Stéphane Chazelas,
 4 #+ modified by Bruno Haible, bugfixed by Alfredo Pironti.
 6 . gettext.sh
8 E CDERROR=65
10 error()
11 {
12 printf "$@" >&2
13 exit $E_CDERROR
14 }
16 cd $var || error "`eval_gettext \"Can\'t cd to \\\$var.\"`"
17 # The triple backslashes (escapes) in front of $var needed
18 #+ "because eval_gettext expects a string
19 #+ where the variable values have not yet been substituted."
20 # -- per Bruno Haible
21 read -p "`gettext \"Enter the value: \"`" var
22 # ...
2.3
24
25 # -----
26 # Alfredo Pironti comments:
28 # This script has been modified to not use the $"..." syntax in
29 #+ favor of the "`gettext \"...\"`" syntax.
30 # This is ok, but with the new localized.sh program, the commands
31 #+ "bash -D filename" and "bash --dump-po-string filename"
32 #+ will produce no output
33 #+ (because those command are only searching for the $"..." strings)!
34 # The ONLY way to extract strings from the new file is to use the
35 # 'xgettext' program. However, the xgettext program is buggy.
37 # Note that 'xgettext' has another bug.
39 # The shell fragment:
40 # gettext -s "I like Bash"
41 # will be correctly extracted, but . . .
42 # xgettext -s "I like Bash"
43 # . . . fails!
44 # 'xgettext' will extract "-s" because
45 #+ the command only extracts the
46 #+ very first argument after the 'gettext' word.
47
48
49 # Escape characters:
51 # To localize a sentence like
52 # echo -e "Hello\tworld!"
```

```
53 #+ you must use
54 # echo -e "`gettext \"Hello\\tworld\"`"
55 # The "double escape character" before the `t' is needed because
56 #+ 'gettext' will search for a string like: 'Hello\tworld'
57 # This is because gettext will read one literal `\')
58 #+ and will output a string like "Bonjour\tmonde",
59 #+ so the 'echo' command will display the message correctly.
61 # You may not use
62 # echo "`gettext -e \"Hello\tworld\"`"
63 #+ due to the xgettext bug explained above.
65
66
67 # Let's localize the following shell fragment:
68 # echo "-h display help and exit"
70 # First, one could do this:
71 # echo "`gettext \"-h display help and exit\"`"
72 # This way 'xgettext' will work ok,
73 #+ but the 'gettext' program will read "-h" as an option!
74 #
75 # One solution could be
76 # echo "`gettext -- \"-h display help and exit\"`"
77 # This way 'gettext' will work,
78 #+ but 'xgettext' will extract "--", as referred to above.
79 #
80 # The workaround you may use to get this string localized is
81 # echo -e "`gettext \"\\0-h display help and exit\"`"
82 \# We have added a \setminus 0 (NULL) at the beginning of the sentence.
83 # This way 'gettext' works correctly, as does 'xgettext.'
84 # Moreover, the NULL character won't change the behavior
85 #+ of the 'echo' command.
```

```
bash$ bash -D localized.sh
"Can't cd to %s."
"Enter the value: "
```

This lists all the localized text. (The -D option lists double-quoted strings prefixed by a \$, without executing the script.)

```
bash$ bash --dump-po-strings localized.sh
#: a:6
msgid "Can't cd to %s."
msgstr ""
#: a:7
msgid "Enter the value: "
msgstr ""
```

The --dump-po-strings option to Bash resembles the -D option, but uses gettext "po" format.

Bruno Haible points out:

Starting with gettext-0.12.2, **xgettext -o - localized.sh** is recommended instead of **bash --dump-po-strings localized.sh**, because **xgettext** . . .

- 1. understands the gettext and eval_gettext commands (whereas bash --dump-po-strings understands only its deprecated \$"..." syntax)
- 2. can extract comments placed by the programmer, intended to be read by the translator.

This shell code is then not specific to Bash any more; it works the same way with Bash 1.x and other /bin/sh implementations.

Now, build a language.po file for each language that the script will be translated into, specifying the *msgstr*. Alfredo Pironti gives the following example:

fr.po:

```
1 #: a:6
2 msgid "Can't cd to $var."
3 msgstr "Impossible de se positionner dans le repertoire $var."
4 #: a:7
5 msgid "Enter the value: "
6 msgstr "Entrez la valeur : "
7
8 # The string are dumped with the variable names, not with the %s syntax,
9 #+ similar to C programs.
10 #+ This is a very cool feature if the programmer uses
11 #+ variable names that make sense!
```

Then, run msgfmt.

msgfmt -o localized.sh.mo fr.po

Place the resulting localized.sh.mo file in the /usr/local/share/locale/fr/LC_MESSAGES directory, and at the beginning of the script, insert the lines:

```
1 TEXTDOMAINDIR=/usr/local/share/locale
2 TEXTDOMAIN=localized.sh
```

If a user on a French system runs the script, she will get French messages.

With older versions of Bash or other shells, localization requires <u>gettext</u>, using the -s option. In this case, the script becomes:

```
1 #!/bin/bash
2 # localized.sh
3
4 E_CDERROR=65
5
6 error() {
7  local format=$1
8  shift
9  printf "$(gettext -s "$format")" "$@" >&2
10  exit $E_CDERROR
11 }
12 cd $var || error "Can't cd to %s." "$var"
13 read -p "$(gettext -s "Enter the value: ")" var
14 # ...
```

The TEXTDOMAIN and TEXTDOMAINDIR variables need to be set and exported to the environment. This should be done within the script itself.

This appendix written by Stéphane Chazelas, with modifications suggested by Alfredo Pironti, and by Bruno Haible, maintainer of GNU gettext.

<u>Prev</u> <u>Home</u> <u>Next</u> Important System Directories History Commands

Advanced Bash-Scripting Guide: An in-depth exploration of the art of shell scripting

<u>Next</u>

Prev

Appendix J. History Commands

The Bash shell provides command-line tools for editing and manipulating a user's *command history*. This is primarily a convenience, a means of saving keystrokes.

Bash history commands:

```
1. history
```

2. **fc**

```
bash$ history
   1 mount /mnt/cdrom
   2 cd /mnt/cdrom
   3 ls
   ...
```

Internal variables associated with Bash history commands:

- 1. \$HISTCMD
- 2. \$HISTCONTROL
- 3. \$HISTIGNORE
- 4. \$HISTFILE
- 5. \$HISTFILESIZE
- 6. \$HISTSIZE
- 7. \$HISTTIMEFORMAT (Bash, ver. 3.0 or later)
- 8. !!
- 9. !\$
- 10.!#
- 11. !N
- 12. !-N
- 13. !STRING
- 14. !?STRING?
- 15. \STRING\string\

Unfortunately, the Bash history tools find no use in scripting.

```
1 #!/bin/bash
2 # history.sh
3 # Attempt to use 'history' command in a script.
4
5 history
6
7 # Script produces no output.
8 # History commands do not work within a script.
```

```
bash$ ./history.sh
(no output)
```

The Advancing in the Bash Shell site gives a good introduction to the use of history commands in Bash.

<u>Prev</u> <u>Next</u>

Appendix K. A Sample .bashrc File

The \sim /.bashrc file determines the behavior of interactive shells. A good look at this file can lead to a better understanding of Bash.

Emmanuel Rouat contributed the following very elaborate .bashrc file, written for a Linux system. He welcomes reader feedback on it.

Study the file carefully, and feel free to reuse code snippets and functions from it in your own .bashrc file or even in your scripts.

Example K-1. Sample .bashrc file

```
3 # PERSONAL $HOME/.bashrc FILE for bash-2.05a (or later)
 5 # Last modified: Tue Apr 15 20:32:34 CEST 2003
 7 # This file is read (normally) by interactive shells only.
 8 # Here is the place to define your aliases, functions and
 9 # other interactive features like your prompt.
10 #
11 # This file was designed (originally) for Solaris but based
12 # on Redhat's default .bashrc file
13 # --> Modified for Linux.
14 # The majority of the code you'll find here is based on code found
15 # on Usenet (or internet).
16 # This bashrc file is a bit overcrowded - remember it is just
17 # just an example. Tailor it to your needs
19 #
22 # --> Comments added by HOWTO author.
23 \# --> And then edited again by ER :-)
26 # Source global definitions (if any)
29 if [ -f /etc/bashrc ]; then
30 . /etc/bashrc # --> Read /etc/bashrc, if present.

Converting DOS Batch Files to
Shell Scripts

Advanced Bash-Scripting Guide: An in-depth exploration of the art of shell scripting

<u>Prev</u> <u>Next</u>

Appendix L. Converting DOS Batch Files to Shell Scripts

Quite a number of programmers learned scripting on a PC running DOS. Even the crippled DOS batch file language allowed writing some fairly powerful scripts and applications, though they often required extensive kludges and workarounds. Occasionally, the need still arises to convert an old DOS batch file to a UNIX shell script. This is generally not difficult, as DOS batch file operators are only a limited subset of the equivalent shell scripting ones.

Table L-1. Batch file keywords / variables / operators, and their shell equivalents

Batch File Operator	Shell Script Equivalent	Meaning
00	\$	command-line parameter prefix
/	-	command option flag
\	/	directory path separator
==	=	(equal-to) string comparison test
! == !	!=	(not equal-to) string comparison test
1		pipe
@	set +v	do not echo current command
*	*	filename "wild card"
>	>	file redirection (overwrite)
>>	>>	file redirection (append)
<	<	redirect stdin
%VAR%	\$VAR	environmental variable
REM	#	comment
NOT	!	negate following test
NUL	/dev/null	"black hole" for burying command output
ECHO	echo	echo (many more option in Bash)
ECHO.	echo	echo blank line
ECHO OFF	set +v	do not echo command(s) following
FOR %%VAR IN (LIST) DO	for var in [list]; do	"for" loop
:LABEL	none (unnecessary)	label
GOTO	none (use a function)	jump to another location in the script
PAUSE	sleep	pause or wait an interval
CHOICE	case or select	menu choice
IF	if	if-test
IF EXIST <i>FILENAME</i>	if [-e filename]	test if file exists
IF !%N==!	if [-z "\$N"]	if replaceable parameter "N" not present
CALL	source or . (dot operator)	"include" another script
COMMAND /C	source or . (dot operator)	"include" another script (same as CALL)
SET	export	set an environmental variable
SHIFT	shift	left shift command-line argument list
SGN	-lt or -gt	sign (of integer)

ERRORLEVEL	\$?	exit status
CON	stdin	"console" (stdin)
PRN	/dev/lp0	(generic) printer device
LPT1	/dev/lp0	first printer device
COM1	/dev/ttyS0	first serial port

Batch files usually contain DOS commands. These must be translated into their UNIX equivalents in order to convert a batch file into a shell script.

Table L-2. DOS commands and their UNIX equivalents

DOS Command	UNIX Equivalent	Effect
ASSIGN	ln	link file or directory
ATTRIB	chmod	change file permissions
CD	cd	change directory
CHDIR	cd	change directory
CLS	clear	clear screen
COMP	diff, comm, cmp	file compare
COPY	ср	file copy
Ctl-C	Ctl-C	break (signal)
Ctl-Z	Ctl-D	EOF (end-of-file)
DEL	rm	delete file(s)
DELTREE	rm -rf	delete directory recursively
DIR	ls -l	directory listing
ERASE	rm	delete file(s)
EXIT	exit	exit current process
FC	comm, cmp	file compare
FIND	grep	find strings in files
MD	mkdir	make directory
MKDIR	mkdir	make directory
MORE	more	text file paging filter
MOVE	mv	move
PATH	\$PATH	path to executables
REN	mv	rename (move)
RENAME	mv	rename (move)
RD	rmdir	remove directory
RMDIR	rmdir	remove directory
SORT	sort	sort file
TIME	date	display system time
TYPE	cat	output file to stdout
XCOPY	ср	(extended) file copy

a crippled counterpart to read.

DOS supports a very limited and incompatible subset of filename <u>wildcard expansion</u>, recognizing only the * and ? characters.

Converting a DOS batch file into a shell script is generally straightforward, and the result ofttimes reads better than the original.

Example L-1. VIEWDATA.BAT: DOS Batch File

```
1 REM VIEWDATA
2
3 REM INSPIRED BY AN EXAMPLE IN "DOS POWERTOOLS"
4 REM BY PAUL SOMERSON
5
6
7 @ECHO OFF
8
9 IF !%1==! GOTO VIEWDATA
10 REM IF NO COMMAND-LINE ARG...
11 FIND "%1" C:\BOZO\BOOKLIST.TXT
12 GOTO EXITO
13 REM PRINT LINE WITH STRING MATCH, THEN EXIT.
14
15 :VIEWDATA
16 TYPE C:\BOZO\BOOKLIST.TXT | MORE
17 REM SHOW ENTIRE FILE, 1 PAGE AT A TIME.
18
19 :EXITO
```

The script conversion is somewhat of an improvement.

Example L-2. viewdata.sh: Shell Script Conversion of VIEWDATA.BAT

```
1 #!/bin/bash
 2 # viewdata.sh
3 # Conversion of VIEWDATA.BAT to shell script.
 5 DATAFILE=/home/bozo/datafiles/book-collection.data
 6 ARGNO=1
8 # @ECHO OFF
                            Command unnecessary here.
10 if [ $# -lt "$ARGNO" ]
                           # IF !%1==! GOTO VIEWDATA
11 then
12 less $DATAFILE
                           # TYPE C:\MYDIR\BOOKLIST.TXT | MORE
13 else
14 grep "$1" $DATAFILE
                           # FIND "%1" C:\MYDIR\BOOKLIST.TXT
15 fi
16
17 exit 0
                            # :EXITO
18
19 # GOTOs, labels, smoke-and-mirrors, and flimflam unnecessary.
20 # The converted script is short, sweet, and clean,
21 #+ which is more than can be said for the original.
```

Ted Davis' <u>Shell Scripts on the PC</u> site has a set of comprehensive tutorials on the old-fashioned art of batch file programming. Certain of his ingenious techniques could conceivably have relevance for shell scripts.

Appendix M. Exercises

M.1. Analyzing Scripts

Examine the following script. Run it, then explain what it does. Annotate the script and rewrite it in a more compact and elegant manner.

```
1 #!/bin/bash
 3 MAX=10000
 6
    for((nr=1; nr<$MAX; nr++))
 7
 8
 9
     let "t1 = nr % 5"
10
     if [ "$t1" -ne 3 ]
     then
11
12
13
      continue
     fi
14
15
     let "t2 = nr % 7"
     if [ "$t2" -ne 4 ]
16
17 then
18
      continue
19
     fi
20
      let "t3 = nr % 9"
21
      if [ "$t3" -ne 5 ]
22
23
      then
24
       continue
      fi
25
26
27
    break # What happens when you comment out this line? Why?
28
29
    done
30
31
   echo "Number = $nr"
32
33
34 exit 0
```

Explain what the following script does. It is really just a parameterized command-line pipe.

```
1 #!/bin/bash
2
3 DIRNAME=/usr/bin
4 FILETYPE="shell script"
5 LOGFILE=logfile
6
7 file "$DIRNAME"/* | fgrep "$FILETYPE" | tee $LOGFILE | wc -1
8
9 exit 0
```

Examine and explain the following script. For hints, you might refer to the listings for find and stat.

```
1 #!/bin/bash
2
3 # Author: Nathan Coulter
4 # This code is released to the public domain.
5 # The author gave permission to use this code snippet in the ABS Guide.
6
```

```
7 find -maxdepth 1 -type f -printf '%f\000' | {
8    while read -d $'\000'; do
9         mv "$REPLY" "$(date -d "$(stat -c '%y' "$REPLY") " '+%Y%m%d%H%M%S'
10         )-$REPLY"
11    done
12 }
13
14 # Warning: Test-drive this script in a "scratch" directory.
15 # It will somehow affect all the files there.
```

A reader sent in the following code snippet.

```
1 while read LINE
2 do
3   echo $LINE
4 done < `tail -f /var/log/messages`</pre>
```

He wished to write a script tracking changes to the system log file, /var/log/messages. Unfortunately, the above code block hangs and does nothing useful. Why? Fix this so it does work. (Hint: rather than redirecting the stdin of the loop, try a pipe.)

Analyze the following "one-liner" (here split into two lines for clarity) contributed by Rory Winston:

```
1 export SUM=0; for f in $(find src -name "*.java");
2 do export SUM=$(($SUM + $(wc -l $f | awk '{ print $1 }'))); done; echo $SUM
```

Hint: First, break the script up into bite-sized sections. Then, carefully examine its use of <u>double-parentheses</u> arithmetic, the <u>export</u> command, the <u>find</u> command, the <u>wc</u> command, and <u>awk</u>.

Analyze Example A-10, and reorganize it in a simplified and more logical style. See how many of the variables can be eliminated, and try to optimize the script to speed up its execution time.

Alter the script so that it accepts any ordinary ASCII text file as input for its initial "generation". The script will read the first \$ROW*\$COL\$ characters, and set the occurrences of vowels as "living" cells. Hint: be sure to translate the spaces in the input file to underscore characters.

Shell Scripts

Advanced Bash-Scripting Guide: An in-depth exploration of the art of shell scripting

<u>Prev</u> Appendix M. Exercises <u>Next</u>

M.2. Writing Scripts

Write a script to carry out each of the following tasks.

EASY

Home Directory Listing

Perform a recursive directory listing on the user's home directory and save the information to a file. Compress the file, have the script prompt the user to insert a floppy, then press **ENTER**. Finally, save the file to the floppy.

Self-reproducing Script

Write a script that backs itself up, that is, copies itself to a file named backup.sh.

Hint: Use the <u>cat</u> command and the <u>appropriate positional parameter</u>.

Converting for loops to while and until loops

Convert the *for loops* in Example 10-1 to *while loops*. Hint: store the data in an <u>array</u> and step through the array elements.

Having already done the "heavy lifting", now convert the loops in the example to *until loops*.

Changing the line spacing of a text file

Write a script that reads each line of a target file, then writes the line back to stdout, but with an extra blank line following. This has the effect of *double-spacing* the file.

Include all necessary code to check whether the script gets the necessary command line argument (a filename), and whether the specified file exists.

When the script runs correctly, modify it to *triple-space* the target file.

Finally, write a script to remove all blank lines from the target file, *single-spacing* it.

Backwards Listing

Write a script that echoes itself to stdout, but backwards.

Automatically Decompressing Files

Given a list of filenames as input, this script queries each target file (parsing the output of the <u>file</u> command) for the type of compression used on it. Then the script automatically invokes the appropriate decompression command (**gunzip**, **bunzip2**, **unzip**, **uncompress**, or whatever). If a target file is not compressed, the script emits a warning message, but takes no other action on that particular file.

Unique System ID

Generate a "unique" 6-digit hexadecimal identifier for your computer. Do *not* use the flawed <u>hostid</u> command. Hint: <u>md5sum</u> /etc/passwd, then select the first 6 digits of output.

Backup

Archive as a "tarball" (*.tar.gz file) all the files in your home directory tree (/home/your-name) that have been modified in the last 24 hours. Hint: use <u>find</u>.

Checking whether a process is still running

Given a <u>process ID</u> (*PID*) as an argument, this script will check, at user-specified intervals, whether the given process is still running. You may use the <u>ps</u> and <u>sleep</u> commands.

Primes

Print (to stdout) all prime numbers between 60000 and 63000. The output should be nicely formatted in columns (hint: use <u>printf</u>).

Lottery Numbers

One type of lottery involves picking five different numbers, in the range of 1 - 50. Write a script that generates five pseudorandom numbers in this range, *with no duplicates*. The script will give the

option of echoing the numbers to stdout or saving them to a file, along with the date and time the particular number set was generated.

INTERMEDIATE

Integer or String

Write a script <u>function</u> that determines if an argument passed to it is an integer or a string. The function will return TRUE (0) if passed an integer, and FALSE (1) if passed a string.

Hint: What does the following expression return when \$1 is *not* an integer?

$$expr $1 + 0$$

Managing Disk Space

List, one at a time, all files larger than 100K in the /home/username directory tree. Give the user the option to delete or compress the file, then proceed to show the next one. Write to a logfile the names of all deleted files and the deletion times.

Removing Inactive Accounts

Inactive accounts on a network waste disk space and may become a security risk. Write an administrative script (to be invoked by *root* or the <u>cron daemon</u>) that checks for and deletes user accounts that have not been accessed within the last 90 days.

Enforcing Disk Quotas

Write a script for a multi-user system that checks users' disk usage. If a user surpasses the preset limit (100 MB, for example) in her /home/username directory, then the script will automatically send her a warning e-mail.

The script will use the <u>du</u> and <u>mail</u> commands. As an option, it will allow setting and enforcing quotas using the <u>quota</u> and <u>setquota</u> commands.

Logged in User Information

For all logged in users, show their real names and the time and date of their last login.

Hint: use who, lastlog, and parse /etc/passwd.

Safe Delete

Write, as a script, a "safe" delete command, srm.sh. Filenames passed as command-line arguments to this script are not deleted, but instead <u>gzipped</u> if not already compressed (use <u>file</u> to check), then moved to a /home/username/trash directory. At invocation, the script checks the "trash" directory for files older than 48 hours and deletes them.

Making Change

What is the most efficient way to make change for \$1.68, using only coins in common circulations (up to 25c)? It's 6 quarters, 1 dime, a nickel, and three cents.

Given any arbitrary command line input in dollars and cents (\$*.??), calculate the change, using the minimum number of coins. If your home country is not the United States, you may use your local currency units instead. The script will need to parse the command line input, then change it to multiples of the smallest monetary unit (cents or whatever). Hint: look at Example 23-8.

Quadratic Equations

Solve a "quadratic" equation of the form $Ax^2 + Bx + C = 0$. Have a script take as arguments the coefficients, **A**, **B**, and **C**, and return the solutions to four decimal places.

Hint: pipe the coefficients to <u>bc</u>, using the well-known formula, $x = (-B + /- sqrt (B^2 - 4AC)) / 2A$.

Sum of Matching Numbers

Find the sum of all five-digit numbers (in the range 10000 - 99999) containing *exactly two* out of the following set of digits: { 4, 5, 6 }. These may repeat within the same number, and if so, they count once for each occurrence.

Some examples of matching numbers are 42057, 74638, and 89515.

Lucky Numbers

A "lucky number" is one whose individual digits add up to 7, in successive additions. For example, 62431 is a "lucky number" (6 + 2 + 4 + 3 + 1 = 16, 1 + 6 = 7). Find all the "lucky numbers" between 1000 and 10000.

Alphabetizing a String

Alphabetize (in ASCII order) an arbitrary string read from the command line.

Parsing

Parse /etc/passwd, and output its contents in nice, easy-to-read tabular form.

Logging Logins

Parse /var/log/messages to produce a nicely formatted file of user logins and login times. The script may need to run as *root*. (Hint: Search for the string "LOGIN.")

Pretty-Printing a Data File

Certain database and spreadsheet packages use save-files with *comma-separated values* (CSVs). Other applications often need to parse these files.

Given a data file with comma-separated fields, of the form:

```
1 Jones, Bill, 235 S. Williams St., Denver, CO, 80221, (303) 244-7989
2 Smith, Tom, 404 Polk Ave., Los Angeles, CA, 90003, (213) 879-5612
3 ...
```

Reformat the data and print it out to stdout in labeled, evenly-spaced columns.

Justification

Given ASCII text input either from stdin or a file, adjust the word spacing to right-justify each line to a user-specified line-width, then send the output to stdout.

Mailing List

Using the <u>mail</u> command, write a script that manages a simple mailing list. The script automatically e-mails the monthly company newsletter, read from a specified text file, and sends it to all the addresses on the mailing list, which the script reads from another specified file.

Generating Passwords

Generate pseudorandom 8-character passwords, using characters in the ranges [0-9], [A-Z], [a-z]. Each password must contain at least two digits.

Monitoring a User

You suspect that one particular user on the network has been abusing his privileges and possibly attempting to hack the system. Write a script to automatically monitor and log his activities when he's signed on. The log file will save entries for the previous week, and delete those entries more than seven days old.

You may use <u>last</u>, <u>lastlog</u>, and <u>lastcomm</u> to aid your surveillance of the suspected malefactor.

Checking for Broken Links

Using lvnx with the -traversal option, write a script that checks a Web site for broken links.

DIFFICULT

Testing Passwords

Write a script to check and validate passwords. The object is to flag "weak" or easily guessed password candidates.

A trial password will be input to the script as a command line parameter. To be considered acceptable, a password must meet the following minimum qualifications:

- ♦ Minimum length of 8 characters
- ♦ Must contain at least one numeric character
- ♦ Must contain at least one of the following non-alphabetic characters: @, #, \$, %, &, *, +, -, =

Optional:

- ♦ Do a dictionary check on every sequence of at least four consecutive alphabetic characters in the password under test. This will eliminate passwords containing embedded "words" found in a standard dictionary.
- ♦ Enable the script to check all the passwords on your system. These may or may not reside in /etc/passwd.

This exercise tests mastery of Regular Expressions.

Cross Reference

Write a script that generates a *cross-reference* (*concordance*) on a target file. The output will be a listing of all word occurrences in the target file, along with the line numbers in which each word occurs. Traditionally, *linked list* constructs would be used in such applications. Therefore, you should investigate <u>arrays</u> in the course of this exercise. <u>Example 15-12</u> is probably *not* a good place to start.

Square Root

Write a script to calculate square roots of numbers using Newton's Method.

The algorithm for this, expressed as a snippet of Bash <u>pseudo-code</u> is:

```
(Isaac) Newton's Method for speedy extraction
 2 #+ of square roots.
 3
 4 guess = $argument
 5 # $argument is the number to find the square root of.
 6 # $quess is each successive calculated "quess" -- or trial solution --
 7 #+ of the square root.
 8 # Our first "guess" at a square root is the argument itself.
10 \text{ oldguess} = 0
11 # $oldguess is the previous $guess.
13 tolerance = .000001
14 # To how close a tolerance we wish to calculate.
16 loopcnt = 0
17 # Let's keep track of how many times through the loop.
18 # Some arguments will require more loop iterations than others.
21 while [ ABS( $guess $oldguess ) -gt $tolerance ]
         ^^^^^^^^^^^^^^ Fix up syntax, of course.
22 #
23
"ABS" is a (floating point) function to find the absolute value of the difference between the two terms.
26 #
               So, as long as difference between current and previous
27 #+
                trial solution (guess) exceeds the tolerance, keep looping.
28
29 do
30
     oldguess = $guess # Update $oldguess to previous $guess.
31
32 # -----
33 guess = ( $oldguess + ( $argument / $oldguess ) ) / 2.0
34 \# = 1/2 ( (\$oldguess **2 + \$argument) / \$oldguess )
     equivalent to:
     = 1/2 ( $oldguess + $argument / $oldguess )
37 # that is, "averaging out" the trial solution and
38 #+ the proportion of argument deviation
39 #+ (in effect, splitting the error in half).
40 # This converges on an accurate solution
41 #+ with surprisingly few loop iterations . . .
42 #+ for arguments > $tolerance, of course.
43 #
44
```

```
45 ((loopcnt++)) # Update loop counter.
46 done
```

It's a simple enough recipe, and *seems* at first glance easy enough to convert into a working Bash script. The problem, though, is that Bash has <u>no native support for floating point numbers</u>. So, the script writer needs to use <u>bc</u> or possibly <u>awk</u> to convert the numbers and do the calculations. It may get rather messy . . .

Logging File Accesses

Log all accesses to the files in /etc during the course of a single day. This information should include the filename, user name, and access time. If any alterations to the files take place, that should be flagged. Write this data as neatly formatted records in a logfile.

Monitoring Processes

Write a script to continually monitor all running processes and to keep track of how many child processes each parent spawns. If a process spawns more than five children, then the script sends an e-mail to the system administrator (or *root*) with all relevant information, including the time, PID of the parent, PIDs of the children, etc. The script appends a report to a log file every ten minutes.

Strip Comments

Strip all comments from a shell script whose name is specified on the command line. Note that the "#! line" must not be stripped out.

Strip HTML Tags

Strip all HTML tags from a specified HTML file, then reformat it into lines between 60 and 75 characters in length. Reset paragraph and block spacing, as appropriate, and convert HTML tables to their approximate text equivalent.

XML Conversion

Convert an XML file to both HTML and text format.

Chasing Spammers

Write a script that analyzes a spam e-mail by doing DNS lookups on the IP addresses in the headers to identify the relay hosts as well as the originating ISP. The script will forward the unaltered spam message to the responsible ISPs. Of course, it will be necessary to filter out *your own ISP's IP address*, so you don't end up complaining about yourself.

As necessary, use the appropriate <u>network analysis commands</u>.

For some ideas, see Example 15-40 and Example A-30.

Optional: Write a script that searches through a list of e-mail messages and deletes the spam according to specified filters.

Creating man pages

Write a script that automates the process of creating man pages.

Given a text file which contains information to be formatted into a *man page*, the script will read the file, then invoke the appropriate <u>groff</u> commands to output the corresponding *man page* to stdout. The text file contains blocks of information under the standard *man page* headings, i.e., "NAME," "SYNOPSIS," "DESCRIPTION," etc.

See Example 15-28.

Morse Code

Convert a text file to Morse code. Each character of the text file will be represented as a corresponding Morse code group of dots and dashes (underscores), separated by whitespace from the next. For example:

```
1 Invoke the "morse.sh" script with "script"
2 as an argument to convert to Morse.
3
4
5 $ sh morse.sh script
```

```
6
7 ... _._. ._. ._. __. _
8 s c r i p t
```

Hex Dump

Do a hex(adecimal) dump on a binary file specified as an argument. The output should be in neat tabular fields, with the first field showing the address, each of the next 8 fields a 4-byte hex number, and the final field the ASCII equivalent of the previous 8 fields.

The obvious followup to this is to extend the hex dump script into a disassembler. Using a lookup table, or some other clever gimmick, convert the hex values into 80x86 op codes.

Emulating a Shift Register

Using Example 26-15 as an inspiration, write a script that emulates a 64-bit shift register as an <u>array</u>. Implement functions to *load* the register, *shift left*, *shift right*, and *rotate* it. Finally, write a function that interprets the register contents as eight 8-bit ASCII characters.

Determinant

Solve a 4 x 4 determinant.

Hidden Words

Write a "word-find" puzzle generator, a script that hides 10 input words in a 10 x 10 matrix of random letters. The words may be hidden across, down, or diagonally.

Optional: Write a script that *solves* word-find puzzles. To keep this from becoming too difficult, the solution script will find only horizontal and vertical words. (Hint: Treat each row and column as a string, and search for substrings.)

Anagramming

Anagram 4-letter input. For example, the anagrams of *word* are: *do or rod row word*. You may use /usr/share/dict/linux.words as the reference list.

Word Ladders

A "word ladder" is a sequence of words, with each successive word in the sequence differing from the previous one by a single letter.

For example, to "ladder" from mark to vase:

```
1 mark --> park --> part --> past --> vast --> vase 2 ^ ^ ^ ^
```

Write a script that solves word ladder puzzles. Given a starting and an ending word, the script will list all intermediate steps in the "ladder." Note that *all* words in the sequence must be legitimate dictionary words.

Fog Index

The "fog index" of a passage of text estimates its reading difficulty, as a number corresponding roughly to a school grade level. For example, a passage with a fog index of 12 should be comprehensible to anyone with 12 years of schooling.

The Gunning version of the fog index uses the following algorithm.

- 1. Choose a section of the text at least 100 words in length.
- 2. Count the number of sentences (a portion of a sentence truncated by the boundary of the text section counts as one).
- 3. Find the average number of words per sentence.

```
AVE_WDS_SEN = TOTAL_WORDS / SENTENCES
```

4. Count the number of "difficult" words in the segment -- those containing at least 3 syllables. Divide this quantity by total words to get the proportion of difficult words.

PRO_DIFF_WORDS = LONG_WORDS / TOTAL_WORDS

5. The Gunning fog index is the sum of the above two quantities, multiplied by 0.4, then rounded to the nearest integer.

```
G_FOG_INDEX = int ( 0.4 * ( AVE_WDS_SEN + PRO_DIFF_WORDS ) )
```

Step 4 is by far the most difficult portion of the exercise. There exist various algorithms for estimating the syllable count of a word. A rule-of-thumb formula might consider the number of letters in a word and the vowel-consonant mix.

A strict interpretation of the Gunning fog index does not count compound words and proper nouns as "difficult" words, but this would enormously complicate the script.

Calculating PI using Buffon's Needle

The Eighteenth Century French mathematician de Buffon came up with a novel experiment. Repeatedly drop a needle of length "n" onto a wooden floor composed of long and narrow parallel boards. The cracks separating the equal-width floorboards are a fixed distance "d" apart. Keep track of the total drops and the number of times the needle intersects a crack on the floor. The ratio of these two quantities turns out to be a fractional multiple of PI.

In the spirit of Example 15-48, write a script that runs a Monte Carlo simulation of Buffon's Needle. To simplify matters, set the needle length equal to the distance between the cracks, n = d.

Hint: there are actually two critical variables: the distance from the center of the needle to the crack nearest to it, and the angle of the needle to that crack. You may use <u>bc</u> to handle the calculations.

Playfair Cipher

Implement the Playfair (Wheatstone) Cipher in a script.

The Playfair Cipher encrypts text by substitution of "digrams" (2-letter groupings). It is traditional to use a 5 x 5 letter scrambled-alphabet *key square* for the encryption and decryption.

```
CODES
 2 A B F G H
3 IKLMN
 4 PQRTU
   VWXYZ
 7 Each letter of the alphabet appears once, except "I" also represents
 8 "J". The arbitrarily chosen key word, "CODES" comes first, then all
 9 the rest of the alphabet, in order from left to right, skipping letters
10 already used.
11
12 To encrypt, separate the plaintext message into digrams (2-letter
13 groups). If a group has two identical letters, delete the second, and
14 form a new group. If there is a single letter left over at the end,
15 insert a "null" character, typically an "X."
16
17 THIS IS A TOP SECRET MESSAGE
18
19 TH IS IS AT OP SE CR ET ME SA GE
20
21 For each digram, there are three possibilities.
23 1) Both letters will be on the same row of the key square
24 For each letter, substitute the one immediately to the right, in that
25
   row. If necessary, wrap around left to the beginning of the row.
26
27 or
28
29 2) Both letters will be in the same column of the key square
   For each letter, substitute the one immediately below it, in that
31
    row. If necessary, wrap around to the top of the column.
32
```

```
33 or
34
35 3) Both letters will form the corners of a rectangle within the key
36 square. For each letter, substitute the one on the other corner the
37
     rectangle which lies on the same row.
38
39
40 The "TH" digram falls under case #3.
41 G H
42 M N
                (Rectangle with "T" and "H" at corners)
43 T U
44
45 T --> U
46 H --> G
47
49 The "SE" digram falls under case #1.
50 C O D E S (Row containing "S" and "E")
51
52 S --> C (wraps around left to beginning of row)
53 E --> S
55 ========
56
57 To decrypt encrypted text, reverse the above procedure under cases #1
58 and #2 (move in opposite direction for substitution). Under case #3,
59 just take the remaining two corners of the rectangle.
61
62 Helen Fouche Gaines' classic work, ELEMENTARY CRYPTANALYSIS (1939), gives a
63 fairly detailed rundown on the Playfair Cipher and its solution methods.
```

This script will have three main sections

- I. Generating the "key square", based on a user-input keyword.
- II. Encrypting a "plaintext" message.
- III. Decrypting encrypted text.

The script will make extensive use of <u>arrays</u> and <u>functions</u>.

--

Please do not send the author your solutions to these exercises. There are better ways to impress him with your cleverness, such as submitting bugfixes and suggestions for improving this book.

Appendix N. Revision History

```
This document first appeared as a 60-page HOWTO in the late spring of 2000. Since then, it has gone through quite a number of updates and revisions. This book could not have been written without the assistance of the Linux community, and especially of the volunteers of the Linux Documentation Project.
```

Here is the e-mail to the LDP requesting permission to submit version 0.1.

```
1 From thegrendel@theriver.com Sat Jun 10 09:05:33 2000 -0700
 2 Date: Sat, 10 Jun 2000 09:05:28 -0700 (MST)
 3 From: "M. Leo Cooper" <thegrendel@theriver.com>
 4 X-Sender: thegrendel@localhost
 5 To: ldp-discuss@lists.linuxdoc.org
 6 Subject: Permission to submit HOWTO
 8 Dear HOWTO Coordinator,
10 I am working on and would like to submit to the LDP a HOWTO on the subject
11 of "Bash Scripting" (shell scripting, using 'bash'). As it happens,
12 I have been writing this document, off and on, for about the last eight
13 months or so, and I could produce a first draft in ASCII text format in
14 a matter of just a few more days.
16 I began writing this out of frustration at being unable to find a
17 decent book on shell scripting. I managed to locate some pretty good
18 articles on various aspects of scripting, but nothing like a complete,
19 beginning-to-end tutorial. Well, in keeping with my philosophy, if all
20 else fails, do it yourself.
22 As it stands, this proposed "Bash-Scripting HOWTO" would serve as a
23 combination tutorial and reference, with the heavier emphasis on the
24 tutorial. It assumes Linux experience, but only a very basic level
25 of programming skills. Interspersed with the text are 79 illustrative
26 example scripts of varying complexity, all liberally commented. There
27 are even exercises for the reader.
29 At this stage, I'm up to 18,000+ words (124k), and that's over 50 pages of
30 text (whew!).
33 I haven't mentioned that I've previously authored an LDP HOWTO, the
34 "Software-Building HOWTO", which I wrote in Linuxdoc/SGML. I don't know
35 if I could handle Docbook/SGML, and I'm glad you have volunteers to do
36 the conversion. You people seem to have gotten on a more organized basis
37 these last few months. Working with Greg Hankins and Tim Bynum was nice,
38 but a professional team is even nicer.
40 Anyhow, please advise.

Revision History To Do List

Advanced Bash-Scripting Guide: An in-depth exploration of the art of shell scripting

Prev Next

Appendix P. To Do List

- A comprehensive survey of <u>incompatibilities between Bash and the classic Bourne shell</u>.
- Same as above, but for the Korn shell (ksh).
- A primer on CGI programming, using Bash.

Here's a simple CGI script to get you started.

Example P-1. Print the server environment

```
1 #!/bin/bash
 2 # May have to change the location for your site.
3 # (At the ISP's servers, Bash may not be in the usual place.)
 4 # Other places: /usr/bin or /usr/local/bin
 5 # Might even try it without any path in sha-bang.
7 # test-cgi.sh
8 # by Michael Zick
9 # Used with permission
10
11
12 # Disable filename globbing.
13 set -f
14
15 # Header tells browser what to expect.
16 echo Content-type: text/plain
17 echo
18
19 echo CGI/1.0 test script report:
20 echo
21
22 echo environment settings:
23 set
24 echo
25
26 echo whereis bash?
27 whereis bash
28 echo
29
30
31 echo who are we?
32 echo ${BASH_VERSINFO[*]}
33 echo
34
35 echo argc is $#. argv is "$*".
36 echo
37
38 # CGI/1.0 expected environment variables.
40 echo SERVER_SOFTWARE = $SERVER_SOFTWARE
41 echo SERVER_NAME = $SERVER_NAME
42 echo GATEWAY_INTERFACE = $GATEWAY_INTERFACE
43 echo SERVER_PROTOCOL = $SERVER_PROTOCOL
44 echo SERVER_PORT = $SERVER_PORT
45 echo REQUEST_METHOD = $REQUEST_METHOD
46 echo HTTP_ACCEPT = "$HTTP_ACCEPT"
47 echo PATH_INFO = "$PATH_INFO"
48 echo PATH_TRANSLATED = "$PATH_TRANSLATED"
49 echo SCRIPT_NAME = "$SCRIPT_NAME"
50 echo QUERY_STRING = "$QUERY_STRING"
51 echo REMOTE_HOST = $REMOTE_HOST
```

```
52 echo REMOTE_ADDR = $REMOTE_ADDR
53 echo REMOTE_USER = $REMOTE_USER
54 echo AUTH_TYPE = $AUTH_TYPE
55 echo CONTENT_TYPE = $CONTENT_TYPE
56 echo CONTENT_LENGTH = $CONTENT_LENGTH
57
58 exit 0
59
60 # Here document to give short instructions.
61 :<<-'_test_CGI_'
62
63 1) Drop this in your http://domain.name/cgi-bin directory.
64 2) Then, open http://domain.name/cgi-bin/test-cgi.sh.
65
66 _test_CGI_
```

Any volunteers?

Appendix Q. Copyright

The *Advanced Bash Scripting Guide* is copyright © 2000, by Mendel Cooper. The author also asserts copyright on all previous versions of this document. [1]

This blanket copyright recognizes and protects the rights of all contributors to this document.

This document may only be distributed subject to the terms and conditions set forth in the Open Publication License (version 1.0 or later), http://www.opencontent.org/openpub/. The following license options also apply.

```
1 A. Distribution of substantively modified versions of this document
       is permitted only under the following provisions.
 4 Al. The modified document must clearly indicate that it is derivative
      of the original Advanced Bash Scripting Guide, and the original
       author, Mendel Cooper, must be listed as the primary author.
 8 A2. The modified or derivative document must clearly indicate which portions
   of the text differ or deviate from the original document. A notice must
      be present, stating that the original author does not necessarily
10
      endorse the changes to the original.
11
12
13 A3. The modified or derivative document must be distributed under this
14
     license, and the original author's copyright, as applicable, may
15
      not be modified.
16
17
18 B. This document, or any modified or derivative version thereof, may
19
      NOT be distributed encrypted or with any form of DRM (Digital Rights
20
       Management) or content control mechanism embedded in it. Nor may this
      document or any derivative thereof be bundled with other DRM-ed works.
2.1
22
23 C. If this document (or any previous version or derivative thereof)
       is made available on a Web or ftp site, then the file(s) must be
25
       publicly accessible. No password or other access restrictions to
       its download may be imposed.
28 D. Distribution of the original work in any standard (paper) book form
29
      requires permission from the copyright holder.
30
31 E. In the event that the author or maintainer of this document cannot
      be contacted, the Linux Documentation Project is authorized to
       take over custodianship of the document and name a new maintainer,
       who would then have the right to update and modify the document.
```

Without *explicit written permission* from the author, distributors and publishers (including on-line publishers) are prohibited from imposing any additional conditions, strictures, or provisions on this document, any previous versions, or any derivative versions. As of this update, the author asserts that he has *not* entered into any contractual obligations that would alter the foregoing declarations.

Essentially, you may freely distribute this book or any derivatives thereof in electronic form.

If you display or distribute this document, any previous versions thereof, or any derivatives thereof under any license except the one above, then you are required to obtain the author's written permission. Failure to do so may terminate your distribution rights.

Additionally, the following waiver applies:

```
2 to use the materials within or any portion thereof in a patent or copyright
3 lawsuit against the Open Source community, its developers, or against any
4 of its associated software or documentation including, but not limited
5 to, the Linux kernel, Open Office, Samba, and Wine. You further waive
6 the right to use any of the materials within this book in testimony or
7 depositions as a plaintiff's "expert witness" in any lawsuit against the
8 Open Source community, any of its developers, or any of its associated
9 software or documentation.
```

These are very liberal terms, and they should not hinder any legitimate distribution or use of this book. The author especially encourages its use for classroom and instructional purposes.

Certain of the scripts contained in this document are, where noted, in the Public Domain. These scripts are exempt from the foregoing license and copyright restrictions.

The commercial print and other rights to this book are available. Please contact the author if interested.

The author produced this book in a manner consistent with the spirit of the <u>LDP Manifesto</u>.

Appendix R. ASCII Table

In a book of this sort it is traditional to have an appendix with an ASCII table. This book does not. Instead, here is a short shell script that generates a complete ASCII table and writes it to the file ASCII.txt.

Example R-1. A script that generates an ASCII table

```
1 #!/bin/bash
 2 # ascii.sh
 4 # Script by Sebastian Arming.
 5 # Lightly modified by ABS Guide author.
 6 # Used with permission (thanks!).
 8 exec >ASCII.txt
                           # Save stdout to file,
                           #+ as in the example scripts
10
                           #+ reassign-stdout.sh and upperconv.sh.
11
12 MAXNUM=256
13 COLUMNS=5
14 OCT=8
15 OCTSQU=64
16 LITTLESPACE=-3
17 BIGSPACE=-5
19 i=1 # Decimal counter
20 o=1 # Octal counter
21
22 while [ "$i" -lt "$MAXNUM" ]; do
         paddi=" $i"
23
          echo -n "${paddi: $BIGSPACE} " # Column spacing.
          paddo="00$o"
25
          echo -ne "\\${paddo: $LITTLESPACE}"
26
           echo -n "
27
28
          if ((i % COLUMNS == 0)); then
29
              echo
30
          fi
31
          ((i++, o++))
          # The octal notation for 8 is 10 and 80 -> 100.
32
          ((i % SOCT == 0)) && ((o+=2))
3.3
          ((i % SOCTSQU == 0)) && ((o+=20))
34
35
          # We don't have to count past 0777.
36 done
37
38 exit 0
```

Advanced Bash-Scripting Guide: An in-depth exploration of the art of shell scripting

Prev

Index

This index / glossary / quick-reference lists many of the important topics covered in the text. Terms are arranged in *approximate* sorting order, reshuffled as necessary for enhanced clarity.

Note that *commands* are indexed in Part 4.

* * *

- ^ (caret) Beginning-of-line, in a Regular Expression
- ~ Tilde
 - ~ home directory, corresponds to \$HOME
 - ~/ Current user's home directory
 - ~+ *Current* working directory
 - ~- Previous working directory
- = Equals sign
 - = <u>Variable assignment</u> operator
 - = <u>String comparison</u> operator
 - == <u>String comparison</u> operator
 - =~ Regular Expression match operator

Example script

- < Left angle bracket
 - Is-less-than

String comparison

<u>Integer comparison</u> within <u>double parentheses</u>

- Redirection
 - < stdin
 - << Here document
 - <<< Here string
 - Opening a file for both reading and writing
- > Right angle bracket
 - Is-greater-than

String comparison

Integer comparison, within double parentheses

• Redirection

- > Redirect stdout to a file
- >> Redirect stdout to a file, but append
- i>&j Redirect file descriptor i to file descriptor j
- >&j Redirect stdout to file descriptor j
- >&2 Redirect stdout of a command to stderr
- 2>&1 Redirect stderr to stdout
- &> Redirect both stdout and stderr of a command to a file
- :> file <u>Truncate file</u> to zero length
- I Pipe, a device for passing the output of a command to another command or to the shell
- Il Logical OR test operator
- (dash)
 - Prefix to default parameter, in parameter substitution
 - Prefix to option flag
 - Indicating redirection from stdin or stdout
 - -- (double-dash)

Prefix to long command options

<u>C-style variable decrement</u> within double parentheses

- ; (semicolon)
 - As command separator
 - \; Escaped semicolon, terminates a find command
 - ;; <u>Double-semicolon</u>, terminator in a <u>case</u> option
 - Required when ...

do keyword is on the first line of loop

terminating curly-bracketed code block

- : Colon, null command, equivalent to the true Bash builtin
 - :> file <u>Truncate file</u> to zero length
- ! Negation operator, inverts exit status of a test or command
 - != not-equal-to String comparison operator
- ? (question mark)
 - Match zero or one characters, in an Extended Regular Expression
 - Single-character wild card, in globbing

• In a *C*-style Trinary operator

// Double forward slash, behavior of cd command toward

- . (dot / period)
 - . Load a file (into a script), equivalent to source command
 - . Match single character, in a Regular Expression
 - . Current working directory
 - J Current working directory
 - .. Parent directory
- '...' (single quotes) strong quoting
- "..." (double quotes) weak quoting
- () Parentheses
 - (...) Command group; starts a subshell
 - (...) Enclose group of Extended Regular Expressions
 - >(...)
 - <(...) Process substitution
 - ...) <u>Terminates test-condition</u> in *case* construct
 - ((...)) <u>Double parentheses</u>, in arithmetic expansion

Left bracket, test construct

[]Brackets

- Array element
- Enclose character set to match in a Regular Expression
- Test construct
- [[...]] <u>Double brackets</u>, extended *test* construct
- \$ Anchor, in a Regular Expression
- **\$** Prefix to a variable name
- \$(...) Command substitution, setting a variable with output of a command, using parentheses notation
- `...` Command substitution, using backquotes notation
- **\${ ... }** Variable manipulation / evaluation
 - **\${var}** <u>Value of a variable</u>
 - \${#var} Length of a variable
 - **\$**{#@}
 - **\${#*}** Number of *positional parameters*
 - \${parameter?err_msg} Parameter-unset message
 - **\${parameter-default}**

```
${parameter:-default}
        ${parameter=default}
        ${parameter:=default} <u>Set default parameter</u>
      • ${parameter+alt_value}
        ${parameter:+alt_value}
        Alternate value of parameter, if set
      • ${!var}
        Indirect referencing of a variable, new notation
      • ${!varprefix*}
        ${!varprefix@}
        Match names of all previously declared variables beginning with varprefix
      • ${string:position}
        ${string:position:length} <u>Substring extraction</u>
      • ${var#Pattern}
        ${var##Pattern} <u>Substring removal</u>
      • ${var % Pattern}
        ${var%%Pattern} Substring removal
      • ${string/substring/replacement}
        ${string//substring/replacement}
        ${string/#substring/replacement}
        ${string/%substring/replacement} Substring replacement
\Escape the character following
      • \< ... \> Angle brackets, escaped, word boundary in a Regular Expression
      • \{ N \} "Curly" brackets, escaped, number of character sets to match in an Extended RE
      • \; <u>Semicolon</u>, escaped, terminates a <u>find</u> command
      • \$$ <u>Indirect reverencing of a variable</u>, old-style notation
      • Escaping a newline, to write a multi-line command
      • &> Redirect both stdout and stderr of a command to a file
      • >&j Redirect stdout to file descriptor j
        >&2 Redirect stdout of a command to stderr
      • i>&j Redirect file descriptor i to file descriptor j
        2>&1 Redirect stderr to stdout
```

&

• Closing file descriptors

- **n<&-** Close input file descriptor *n*
- **0<&-, <&-** Close stdin
- **n>&-** Close output file descriptor *n*
- 1>&-, >&- Close stdout
- && Logical AND test operator
- Command & Run job in background
- # Hashmark, special symbol beginning a script comment
- #! Sha-bang, special string starting a shell script
- * Asterisk
 - Wild card, in globbing
 - Any number of characters in a Regular Expression
 - ** Exponentiation, arithmetic operator
- % Percent sign
 - Modulo, division-remainder arithmetic operation
 - <u>Substring removal</u> (pattern matching) operator
- + Plus sign
 - Character match, in an extended Regular Expression
 - <u>Prefix to alternate parameter</u>, in parameter substitution
 - ++ <u>C-style variable increment</u>, within *double parentheses*

* * *

Shell Variables

- **\$** Last argument to previous command
- \$- Flags passed to script, using set
- \$! Process ID of last background job
- **\$?** Exit status of a command
- \$@ All the positional parameters, as separate words
- **\$*** All the *positional parameters*, <u>as a *single* word</u>
- \$\$ Process ID of the script
- \$# Number of arguments passed to a function, or to the script itself
- **\$0** Filename of the script
- \$1 First argument passed to script

\$9 Ninth argument passed to script

Table of shell variables

* * * * * *

-a Logical AND compound comparison test

Advanced Bash Scripting Guide, where to download

Alias

• Removing an alias, using unalias

And list

• To supply default command-line argument

Angle brackets, escaped, \<...\> word boundary in a Regular Expression

Anonymous here document, using:

Arithmetic expansion

• variations of

Arithmetic operators

• combination operators, C-style

In certain contexts, += can also function as a string concatenation operator.

Arrays

- Bracket notation
- Concatenating, example script
- Copying
- Declaring

declare -a array_name

- Embedded arrays
- Empty arrays, empty elements, example script
- Indirect references
- Initialization

```
array=( element1 element2 ... elementN)
```

Example script

Using command substitution

- Loading a file into an array
- Multidimensional, simulating

- Nesting and embedding
- Notation and usage
- Number of elements in

```
${#array_name[@]}
${#array_name[*]}
```

- Operations
- Passing an array to a function
- As <u>return value from a function</u>
- Special properties, example script
- String operations, example script
- unset deletes array elements

ASCII table

awk field-oriented text processing language

- rand (), random function
- String manipulation
- <u>Using export</u> to pass a variable to an embedded awk script

* * *

Backquotes, used in command substitution

Base conversion, example script

Bash

- Bad scripting practices
- Basics reviewed, script example
- Command-line options

Table

- Features that classic Bourne shell lacks
- Internal variables
- Version 2
- Version 3

.bashrc

\$BASH SUBSHELL

Basic commands, external

Batch processing

bc, calculator utility

- <u>In a here document</u>
- <u>Template</u> for calculating a script variable

Bibliography

Bison utility

Bitwise operators

Blocks of code

• Redirection

Script example: redirecting output of a a code block

Brace expansion

• <u>Extended</u>, {a..z}

Brackets, []

- Array element
- Enclose character set to match in a Regular Expression
- Test construct

Brackets, curly, {}, used in

- Code block
- <u>find</u>
- Extended Regular Expressions
- <u>Positional parameters</u>
- xargs

break loop control command

• Parameter (optional)

Builtins in Bash

• Do not fork a subprocess

* * *

case construct

- Command-line parameters, handling
- Globbing, filtering strings with

cat, concatentate file(s)

- Abuse of
- cat scripts
- Less efficient than redirecting stdin
- Piping the output of, to a read
- Uses of

Child processes

Colon,:, equivalent to the true Bash builtin

Colorizing scripts

- <u>Table</u> of color escape sequences
- Template, colored text on colored background

<u>Comma operator</u>, linking commands or operations

Command-line options

Command substitution

- <u>\$(...)</u>, preferred notation
- <u>Backquotes</u>
- Extending the *Bash* toolset
- Invokes a subshell
- Nesting
- Removes trailing newlines
- Setting variable from loop output
- Word splitting

Comment headers, special purpose

Commenting out blocks of code

- Using an *anonymous* here document
- Using an <u>if-then</u> construct

Compound comparison operators

continue loop control command

Control characters

- Control-C, break
- Control-D, terminate / log out / erase
- Control-H, rubout
- Control-M, Carriage return

<u>C-style syntax</u>, for handling variables

Curly brackets {}

- in *find* command
- in an Extended Regular Expression
- in xargs

* * *

Daemons, in UNIX-type OS

date

dc, calculator utility

dd, data duplicator command

- Conversions
- Copying raw data to/from devices
- File deletion, secure
- Keystrokes, capturing
- Options
- Random access on a data stream
- Swapfiles, initializing
- Thread on www.linuxquestions.org

Debugging scripts

- Tools
- Trapping at exit
- Trapping signals

Decimal number, Bash interprets numbers as

declare builtin

• options

Default parameters

/dev directory

- /dev/null pseudo-device file
- <u>/dev/urandom</u> pseudo-device file, generating pseudorandom numbers with
- /dev/zero, pseudo-device file

dialog, utility for generating dialog boxes in a script

\$DIRSTACK directory stack

Disabled commands, in restricted shells

do keyword, begins execution of commands within a loop

done keyword, terminates a loop

DOS batch files, converting to shell scripts

DOS commands, UNIX equivalents of (table)

dot files, "hidden" setup and configuration files

Double brackets [[...]] test construct

Double quotes " ... " weak quoting

Double-spacing a text file, using sed

-e File exists test

<u>echo</u>

- Feeding commands down a pipe
- Setting a variable using command substitution
- /bin/echo, external echo command

elif, Contraction of else and if

esac, keyword terminating case construct

Environmental variables

-eq, is-equal-to integer comparison test

Eratosthenes, Sieve of, algorithm for generating prime numbers

Escaped characters, special meanings of

\$EUID, Effective user ID

eval, Combine and evaluate expression(s), with variable expansion

- Effects of, Example script
- Forces reevaluation of arguments
- Risk of using

exec command, using in redirection

Exercises

Exit and Exit status

- exit command
- Exit status (exit code, return status of a command)

<u>Table</u>, *Exit codes* with special meanings

Out of range

Specified by a function return

Successful, 0

Export, to make available variables to child processes

• Passing a variable to an embedded awk script

expr, Expression evaluator

- <u>Substring extraction</u>
- <u>Substring index</u> (numerical position in string)
- Substring matching

Extended Regular Expressions

- ? (question mark) Match zero / one characters
- (...) Group of expressions
- \{ N \} "Curly" brackets, escaped, number of character sets to match
- + Character match

* * *

false, returns unsuccessful (1) exit status

File descriptors

• Closing

n<&- Close input file descriptor *n*

0<&-, **<&-** Close stdin

n>&- Close output file descriptor *n*

1>&-, >&- Close stdout

• File handles in C, similarity to

find

- {} Curly brackets
- \; <u>Escaped</u> semicolon

Filter, feeding output back to same filter

Floating point numbers, Bash does not recognize

fold, a filter to wrap lines of text

Forking a child process

for loops

Functions

- Arguments passed referred to by position
- Capturing the return value of a function using echo
- <u>Definition must precede</u> first call to function
- Exit status
- Local variables

and recursion

- Passing an array to a function
- Passing pointers to a function
- Recursion
- Redirecting stdin of a function
- return

Returning an array from a function

return range limits, workarounds

• *shift* arguments passed to a function

* * *

getopt, external command for parsing script command-line arguments

• Emulated in a script

getopts, Bash builtin for parsing script command-line arguments

• \$OPTIND / \$OPTARG

Globbing, filename expansion

-ge, greater-than or equal integer comparison test

<u>-gt</u>, *greater-than* <u>integer comparison</u> test

\$GROUPS, Groups user belongs to

* * *

Hashing, creating lookup keys in a table

• Example script

head, echo to stdout lines at the beginning of a text file

help, gives usage summary of a Bash builtin

Here documents

• Anonymous here documents, using:

Commenting out blocks of code

Self-documenting scripts

- bc in a here document
- cat scripts
- Command substitution
- ex scripts
- *Function*, supplying input to
- *Here* strings

Prepending text

Using read

• Limit string

Closing *limit string* may not be indented

Dash option to limit string, <<-LimitString</pre>

- Literal text output, for generating program code
- Parameter substitution

Disabling parameter substitution

- Passing parameters
- Temporary files
- <u>Using vi non-interactively</u>

History commands

\$HOME, user's home directory

Homework assignment solver

\$HOSTNAME, system host name

* * *

if [condition]; then ... test construct

• if-grep, if and grep in combination

Fixup for *if-grep* test

\$IFS, Internal field separator variable

• Defaults to whitespace

Integer comparison operators

in, keyword preceding [list] in a for loop

Initialization table, /etc/inittab

Interactive script, test for

I/O redirection

Indirect referencing of variables

- New notation, introduced in version 2 of Bash
- Example script

Iteration

* * *

Job IDs, table

jot, Emit a sequence of integers. Equivalent to seq.

• Random sequence generation

Keywords

kill, terminate a process by process ID

• <u>Options</u> (−1, −9)

killall, terminate a process by name

killall script in /etc/rc.d/init.d

* * *

-le, less-than or equal integer comparison test

let, setting and carrying out arithmetic operations on variables

Limit string, in a here document

<u>\$LINENO</u>, variable indicating the *line number* where it appears in a script

<u>Link</u>, file (using *ln* command)

- Invoking script with multiple names, using ln
- symbolic links, ln -s

List constructs

- And list
- *Or* list

Local variables

• and recursion

Localization

Logical operators (&&, | |, etc.)

Logout file, the ~/.bash_logout file

Loops

- break loop control command
- continue loop control command
- *C*-style loop within <u>double parentheses</u>

for loop

while loop

- do (keyword), begins execution of commands within a loop
- done (keyword), terminates a loop
- for loops

```
for arg in [list]; do
       Command substitution to generate [list]
       Filename expansion in [list]
       Multiple parameters in each [list] element
       Omitting [list], defaults to positional parameters
       Parameterizing [list]
       Redirection
     • in, (keyword) preceding [list] in a for loop
     • Nested loops
     • Running a loop in the background, script example
     • Semicolon required, when do is on first line of loop
       for loop
       while loop
     • until loop
       until [ condition-is-true ]; do
     • while loop
       while [ condition ]; do
       Function call inside test brackets
       Multiple conditions
       Omitting test brackets
       Redirection
       while read construct
     • Which type of loop to use
Loopback devices
     • In /dev directory
     • Mounting an ISO image
-lt, less-than integer comparison test
m4, macro processing language
$MACHTYPE, Machine type
```

Magic number, marker at the head of a file indicating the file type

* * *

Makefile, file containing the list of dependencies used by make command Modulo, arithmetic remainder operator • Application: Generating prime numbers Mortgage calculations, example script * * * -n String not null test Named pipe, a temporary FIFO buffer • Example script nc, netcat, a toolkit for TCP and UDP ports -ne, not-equal-to integer comparison test Negation operator, !, reverses the sense of a test netstat, Network statistics nl, a filter to number lines of text *Noclobber*, -C option to Bash to prevent overwriting of files null variable assignment, avoiding * * * -o Logical OR compound comparison test od, octal dump **SOLDPWD** Previous working directory Operator • Definition of • Precedence Options, passed to shell or script on command line or by set command Or list

Or logical operator, II

* * *

Parameter substitution

 $\bullet \ \$\{parameter + alt_value\}$

```
${parameter:+alt_value}
 Alternate value of parameter, if set
• ${parameter-default}
 ${parameter:-default}
 ${parameter=default}
 ${parameter:=default}
 Default parameters
• ${!varprefix*}
```

\${!varprefix@}

Parameter name match

• \${parameter?err_msg}

Parameter-unset message

• *\${parameter}*

Value of parameter

- Script example
- <u>Table</u> of parameter substitution

Parent / child process problem, a child process cannot export variables to a parent process

Parentheses

- Command group
- Enclose group of Extended Regular Expressions
- Double parentheses, in arithmetic expansion

SPATH, the *path* (location of system binaries)

<u>Perl</u>, programming language

- Combined in the same file with a Bash script
- Embedded in a Bash script
- Using eval with

PID, process ID

Pipe, I, a device for passing the output of a command to another command or to the shell

- Avoiding unnecessary commands in a pipe
- Pipefail, set -o pipefail option to indicate exit status within a pipe
- <u>\$PIPESTATUS</u>, exit status of last executed pipe
- Piping output of a command to a script
- Redirecting stdin, rather than using cat in a pipe

Pitfalls

- <u>- (dash) is *not* redirection operator</u>
- // (double forward slash), behavior of cd command toward
- <u>#!/bin/sh</u> script header disables <u>extended Bash</u> features
- Abuse of *cat*
- <u>CGI programming</u>, using scripts for
- Closing limit string in a here document, indenting
- DOS-type newlines (\r\n) crash a script
- eval, risk of using
- Execute permission lacking for commands within a script
- Export problem, child process to parent process
- Extended Bash features not available
- Failing to *quote* variables within *test* brackets
- <u>GNU command set</u>, in cross-platform scripts
- *null* variable assignment
- Numerical and string comparison operators not equivalent

= and -eq not interchangeable

- Omitting terminal semicolon, in a curly-bracketed code block
- Piping

echo to a loop

echo to *read*

tail –f to *grep*

- suid commands inside a script
- <u>Undocumented Bash features</u>, danger of
- <u>Uninitialized variables</u>
- Variable names, inappropriate
- <u>Variables in a subshell</u>, scope limited
- Whitespace, misuse of

Portability issues in shell scripting

- Setting path and umask
- <u>Using whatis</u>

Positional parameters

- <u>\$@</u>, as *separate* words
- <u>\$*</u>, as a *single* word

POSIX, Portable Operating System Interface / UNIX

• Character classes

\$PPID, process ID of parent process

Precedence, operator

<u>Prepending</u> lines at head of a file, script example

Prime numbers

- Generating primes without using arrays
- Sieve of Eratosthenes

printf, formatted print command

/proc directory

- Running processes, files describing
- Writing to files in /proc, warning

Process

• Process ID (PID)

Process substitution

- To compare contents of directories
- To supply stdin of a command
- Template

Prompt

- <u>\$P\$1</u>, *Main prompt*, seen at command line
- <u>\$PS2</u>, Secondary prompt

Pseudo-code, as problem-solving method

\$PWD, Current working directory

* * *

Question mark,?

- Character match in an Extended Regular Expression
- Single-character wild card, in globbing
- In a *C*-style Trinary operator

Quoting

- Character string
- Variables

within test brackets

• Whitespace, using quoting to preserve

* * *

Random numbers

- /dev/urandom
- rand(), random function in awk
- <u>\$RANDOM</u>, Bash function that returns a pseudorandom integer
- Random sequence generation, using date command
- Random sequence generation, using jot

• Random string, generating

<u>rcs</u>

read, set value of a variable from stdin

- <u>Detecting arrow keys</u>
- Options
- Piping output of *cat* to *read*
- "Prepending" text
- <u>Problems piping echo</u> to read
- Redirection from a file to read
- **SREPLY**, default *read* variable
- <u>Timed input</u>
- while read construct

Recursion

- Factorial
- Fibonacci sequence
- Local variables
- Script calling itself recursively
- Towers of Hanoi

Redirection

- Code blocks
- exec <filename,</pre>

to reassign file descriptors

- <u>Introductory-level explanation</u> of *I/O redirection*
- Open a file for both reading and writing

<>filename

- <u>read input redirected</u> from a file
- <u>stderr to</u> <u>stdout</u>

2>&1

- stdin / stdout, using -
- stdinof a function
- stdout to a file

> ... >>

• stdout to file descriptor j

>& j

• file descriptori to file descriptor j

i>&j

• stdout of a command to stderr

>&2

• stdout and stderr of a command to a file

• tee, redirect to a file output of command(s) partway through a pipe

Reference Cards

- Miscellaneous constructs
- Parameter substitution/expansion
- Special shell variables
- String operations
- Test operators

Binary comparison

Files

Regular Expressions

- ^ (caret) Beginning-of-line
- \$ (dollar sign) Anchor
- . (dot) Match single character
- * (asterisk) Any number of characters
- [] (brackets) Enclose character set to match
- \ (backslash) Escape, interpret following character literally
- \< ... \> (angle brackets, escaped) Word boundary
- Extended REs
 - + Character match

\{\\} Escaped "curly" brackets

[::] POSIX character classes

\$REPLY, Default value associated with read command

Restricted shell, shell (or script) with certain commands disabled

return, command that terminates a function

run-parts

• Running scripts in sequence, without user intervention

* * *

Scope of a variable, definition

Script options, set at command line

Scripting routines, library of useful definitions and functions

Secondary prompt, \$PS2

Security issues

- nmap, network mapper / port scanner
- sudo
- suid commands inside a script
- Viruses, trojans, and worms in scripts
- Writing secure scripts

sed, pattern-based programming language

- Table, basic operators
- Table, examples of operators

select, construct for menu building

• in list omitted

Semicolon required, when do keyword is on first line of loop

• When terminating *curly-bracketed* code block

seq, Emit a sequence of integers. Equivalent to jot.

set, Change value of internal script variables

Shell script, definition of

Shell wrapper, script embedding a command or utility

shift, reassigning positional parameters

\$SHLVL, shell level, depth to which the shell (or script) is nested

shopt, change shell options

Signal, a message sent to a process

Simulations

- Brownian motion
- Galton board
- Horserace
- *Life*, game of
- PI, approximating by firing cannonballs
- Pushdown stack

Single quotes (' ... ') strong quoting

Socket, a communication node associated with an I/O port

Sorting

- Bubble sort
- <u>Insertion sort</u>

source, execute a script or, within a script, import a file

• Passing positional parameters

Spam, dealing with

- Example script
- Example script
- Example script
- Example script

Special characters

Stack, emulating a push-down, Example script

Startup files, Bash

stdin and stdout

Strings

- =~ <u>String match operator</u>
- Comparison
- Length

\${#string}

- Manipulation
- Manipulation, using awk
- Protecting strings from expansion and/or reinterpretation, script example

Unprotecting strings, script example

• Substring extraction

\${string:position}

\${string:position:length}

Using expr

- <u>Substring index</u> (numerical position in string)
- <u>Substring matching</u>, using <u>expr</u>
- Substring removal

\${var#Pattern}

\${var##Pattern}

\${var%Pattern}

\${var%%Pattern}

• Substring replacement

\${string/substring/replacement}

\${string//substring/replacement}

\${string/#substring/replacement}

\$\{\string/\%\substring/\replacement\}

Script example

• <u>Table</u> of *string/substring* manipulation and extraction operators

Strong quoting ' ... '

Stylesheet for writing scripts

Subshell

- Command list within parentheses
- Variables, \$BASH_SUBSHELL and \$SHLVL
- Variables in a *subshell*

scope limited, but ...

... can be accessed outside the subshell?

su Substitute user, log on as a different user or as root

suid (set user id) file flag

• suid commands inside a script, not advisable

Symbolic links

Swapfiles

* * *

tail, echo to stdout lines at the (tail) end of a text file

tee, redirect to a file output of command(s) partway through a pipe

Terminals

- setserial
- <u>setterm</u>
- stty
- wall

test command

- Bash builtin
- external command, /usr/bin/test (equivalent to /usr/bin/[)

Test constructs

Test operators

- -a Logical AND compound comparison
- -e File exists
- -eq <u>is-equal-to</u> (integer comparison)

- -f File is a regular file
- -ge greater-than or equal (integer comparison)
- -gt greater-than (integer comparison)
- -le <u>less-than or equal</u> (integer comparison)
- -lt <u>less-than</u> (integer comparison)
- -n not-zero-length (string comparison)
- -ne not-equal-to (integer comparison)
- -o Logical OR compound comparison
- -u suid flag set, file test
- -z <u>is-zero-length</u> (string comparison)
- = $\underline{\text{is-equal-to}}$ (string comparison)
 - == <u>is-equal-to</u> (string comparison)
- < <u>less-than</u> (string comparison)
- < <u>less-than</u>, (integer comparison, within <u>double parentheses</u>)
- <= <u>less-than-or-equal</u>, (integer comparison, within *double parentheses*)
- > greater-than (string comparison)
- > greater-than, (integer comparison, within *double parentheses*)
- >= <u>greater-than-or-equal</u>, (integer comparison, within *double parentheses*)
- Il Logical OR
- && Logical AND
- •! Negation operator, inverts exit status of a test

!= not-equal-to (string comparison)

• Tables of test operators

Binary comparison

File

Timed input

- <u>Using read -t</u>
- Using stty
- Using timing loop
- Using \$TMOUT

Tips and hints for Bash scripts

- Array, as return value from a function
- Comment blocks

Using anonymous here documents

Using <u>if-then</u> constructs

- Comment headers, special purpose
- C-style syntax, for handling variables
- Double-spacing a text file
- Filenames prefixed with a dash, removing
- Filter, feeding output back to same filter
- Function <u>return</u> value workarounds
- *if-grep* test fixup
- Library of useful definitions and functions
- null variable assignment, avoiding

- Passing an array to a function
- Prepending lines at head of a file
- Pseudo-code
- Script as embedded command
- rcs
- Running scripts in sequence without user intervention, using <u>run-parts</u>
- Script *portability*

Setting path and umask

Using whatis

- Setting script variable to a block of embedded sed or awk code
- Subshell variable, accessing outside the subshell
- Testing a variable to see if it contains only digits
- Tracking script usage
- Widgets, invoking from a script

\$TMOUT, Timeout interval

tr, character translation filter

- DOS to Unix text file conversion
- Options
- Soundex, example script
- <u>Variants</u>

Trap, specifying an action upon receipt of a signal

Trinary operator, C-style

true, returns successful (0) exit status

typeset builtin

• options

* * *

\$UID, User ID number

unalias, to remove an alias

uname, output system information

<u>Uninitialized variables</u>

uniq, filter to remove duplicate lines from a sorted file

unset, delete a shell variable

until loop

until [condition-is-true]; do

Variables

- Array operations on
- Assignment

Script example

Script example

Script example

- Bash internal variables
- Block of sed or awk code, setting a variable to
- C-style increment/decrement/trinary operations
- Change value of internal script variables using set
- <u>declare</u>, to restrict the properties of variables
- Deleting a shell variable using unset
- Environmental
- Expansion / Substring replacement operators
- Indirect referencing

eval variable1=\\$\$variable2

Newer notation

\${!variable}

• Length

\${#var}

- lvalue
- Manipulating and expanding
- Name and value of a variable, distinguishing between
- null variable assignment, avoiding
- Quoting

within test brackets

to preserve whitespace

- rvalue
- Setting to null value
- In *subshell* not visible to parent shell
- Testing a variable <u>if it contains only digits</u>
- <u>Undeclared</u>, error message
- Uninitialized
- **Unsetting**
- <u>Untyped</u>

* * *

wait, suspend script execution

• To remedy script hang

Weak quoting " "
while loop
while [condition]; do
• while read construct
Whitespace, spaces, tabs, and newline characters
 \$IFS defaults to Inappropriate use of Preceding closing limit string in a here document, error Preceding script comments Quoting, to preserve whitespace within strings or variables
who, information about logged on users
